FINIX - Fuel behavior model and interface for multiphysics applications - Code documentation for version 0.17.12

Authors: Henri Loukusa, Ville Valtavirta
Confidentiality: Public
Summary
The FINIX fuel behavior code has been updated to version 0.17.12. In the new version several steady-state models have been implemented, and a new steady-state temperature solver has been developed. The new steady state models are a fission gas release model, fuel grain growth model, fuel swelling and densification models, a cladding creep model, a cladding failure model and a radial power distribution model.

The FINIX code has been designed to provide a fuel behavior module for other calculation codes in multiphysics simulations. The intended use is the improvement of fuel behavior description in neutronics, thermal hydraulics and reactor dynamics codes, without having to employ full-scale fuel performance codes. FINIX couples with the host code on a source code level, and provides an interface of functions that can be used to access the fuel behavior model from the host code. At VTT, FINIX has been integrated into the Monte Carlo reactor physics code Serpent 2, and reactor dynamics codes TRAB-1D, TRAB3D and HEXTRAN.

FINIX consists of several interconnected models that describe the thermo-mechanical behavior of the fuel rod. FINIX solves the transient or steady-state heat equation, with couplings to the cladding and pellet mechanical behavior through the gap conductance and pressure. Publicly available experimental correlations are used for the material properties, and simple models for the heat transfer from the cladding to the coolant have been included.

FINIX has been verified against the FRAPTRAN and FRAPCON fuel performance codes in RIA and steady-state scenarios, and compared against experimental Halden reactor data. Results indicate good agreement with the FRAPTRAN and FRAPCON codes and experimental measurements. Limitations of the present version in the simulated scenarios have also been identified.

1. Introduction

The assessment of the performance of a fuel rod in the reactor core is an integral part of the design, operation, and safety analysis of the nuclear reactor. To study the behavior of the fuel rod, one typically resorts to using a model in one of the two extremes. On one end are the dedicated fuel performance codes, which take into account the multitude of physical phenomena involved in the thermo-mechanical behavior of the fuel rod: diffusion of heat, elastic and plastic deformation of the pellet and the cladding, release of gaseous fission products into the free volume, the interplay of the gas pressure with the mechanical solution of the pellet and the cladding, the feed-back of the deformations and temperatures to the gap heat conductance, the effect of the cladding surface heat flux to the heat transfer into the surrounding coolant, and so on. All of this is done with a complex, interconnected model, where experimental correlations are used to model the dependencies of the material properties on temperature, pressure, burn-up, etc. On the other end of the spectrum are the models used within, e.g., many thermal-hydraulics or neutronics codes, which are based on simple correlations, non-mechanical thermal elements, or even fixed values of temperature. Although they are quick to understand and efficient to solve, such fuel models may be less-than-realistic in, for instance, transient conditions or, in cases where fuel with extended burn-up should be considered.

The purpose of this work is to develop a fuel performance model to be used in a multiphysics context, allowing it to be coupled to existing thermal-hydraulics, reactor dynamics or neutronics codes used at VTT, such as TRAB, HEXTRAN and SERPENT. The scope of the FINIX code is somewhere between the full-fledged fuel performance codes and the simple thermal element: although FINIX employs many of the same experimental correlations as the full fuel performance codes, and solves the thermal and mechanical behavior of the rod, several simplifications have been made, both to improve the performance of the code, and to expedite its development. These assumptions and approximations are discussed in Section 2.2.

In the first stage of development, the aim was to develop a model that is capable of solving the transient heat equation, with couplings to the cladding and pellet mechanical behavior through the gap conductance and pressure. In the current second stage of development, models and correlations required for simulation of extended irradiation periods are implemented, and a steady-state heat equation solver has been developed. Experimental correlations are used for the material properties, and simple models for the heat transfer from the cladding to the coolant have been included. The latter can also be easily replaced by the coupling to a thermal-hydraulics code. The physical models, correlations and their numerical implementation is described in Sections 3–7.

The FINIX code has been designed so that it can be coupled on a source-code level, so that passing input and output files between the codes is not necessary. FINIX includes a collection of built-in functions that can be used for basic setup of the system, and for running the actual simulations, using a fairly high-level syntax. In addition, FINIX has an error message system that can be used to detect beyond-normal operation of the code without aborting program execution. The usage of this high-level interface is described in Section 8. Because of the direct coupling on a source-code level, FINIX allows for low-level (detailed) control of its input and output. Since FINIX-0.15.6, input and output files for stand-alone usage have been defined and examples are provided with the code.

Assessment of the FINIX-0.13.9 code without external coupling is presented in a separate report [1], with a summary of the results given in Section 9 of this report. FINIX is compared with the FRAPTRAN fuel performance code in several RIA scenarios, and with experimental Halden reactor data. The results show good agreement both with FRAPTRAN and the experiments. Known limitations of FINIX are also discussed in Section 9 and in the validation report [1]. Validation of FINIX-0.17.12 is to be performed in the future.
2. General model description

2.1 Version

2.1.1 Current version

This document describes version 0.17.12 of the FINIX fuel behavior model. The version number follows the convention where the first number identifies the general stage of development ("0" for early development stage) and the following numbers identify the date of release (year followed by month).

2.1.2 Version history

The following versions of FINIX have been released:
FINIX-0.13.1 (January 2013, reported in Ref. [2]).
FINIX-0.13.9 (September 2013, reported in Ref. [3]).
FINIX-0.15.6 (June 2015, reported in Ref. [4]).
FINIX-0.15.12 (December 2015, reported in Ref. [5]).
FINIX-0.17.12 (December 2017, this report).

2.2 Model assumptions and approximations

2.2.1 Geometry

The FINIX model solves the heat equation and the cladding mechanical behavior in cylindrical geometry. Furthermore, the heat equation is solved in one dimension, with the temperature having dependence only on the radial coordinate $r$. The azimuthal ($\theta$-) dependence is completely neglected (implying also the assumption that the central axes of the pellet and the cladding are the same), and the axial ($z$-) dependence is only included by solving the heat equation independently for several axial slices, or nodes. However, there is no heat flux between the neighboring axial nodes. Therefore, the model is only applicable to scenarios where the axial heat transfer is small compared to the radial heat transfer, and where the boundary conditions and the power distribution are symmetric with respect to the azimuthal rotations.

The rod internal pressure is calculated by taking into account the deformations and temperatures of all axial nodes, and is assumed equal throughout the axial length of the rod. Coupled with the one dimensional treatment of the heat equation, this constitutes the so-called $1\frac{1}{2}$-dimensional model.

2.2.2 Fuel pellet

The fuel pellet is assumed mechanically rigid, so that it has no response to external stresses. The effect of accumulated burn-up to material property correlations is taken into account, where appropriate.
The pellet is assumed to be perfectly cylindrical for the purposes of the solution of the heat equation – specifically, dishing, chamfers or hourglassing is not taken into account. In calculating the axial strain, the mechanical connection between consecutive pellets is assumed to occur at the centerline – a more realistic modeling of the pellet shape remains to be implemented.

FINIX supports externally given fuel swelling, densification and relocation strains. Radial pellet relocation, fuel swelling and densification can also be calculated from correlations.

### 2.2.3 Cladding

The mechanical model of the cladding is based on the thick cylindrical shell approximation. The model assumes, for example, that the radial differences in stresses and temperatures across the cladding are small. In addition, the model is valid only when the axial curvature of the cladding is small, i.e., when there is very little bowing or bending of the cladding.

The cladding mechanical response is assumed to be elasto-plastic. As of version 0.13.9, plastic strains can be externally given to FINIX, and as of version 0.15.12, time-independent plastic deformation is modeled in accordance with the infinitesimal strain theory, and as of version 0.17.12 plastic deformations due to low-temperature creep are modeled. The model is inadequate to model high strain ruptures as only simple failure models are implemented. Ballooning or other large deformations are not be correctly modeled, as these are incorrectly described by the infinitesimal strain theory.

Oxide formation of the cladding is not modeled, although the effect of the oxide layer is included in the material correlations, where appropriate.

### 2.2.4 Fill gas and FGR

The amount of fill gas and fractions of individual species can be given as input. Material correlations for helium, argon, krypton, xenon, hydrogen, nitrogen and water vapor are available.

The release of fission gases is modeled. Material changes in the pellet due to accumulating fission products are also taken into account in solid and gaseous fission product swelling, and the evolution of the composition of the fill gas due to fission gas release is modeled.

### 2.3 Changes from previous versions

#### 2.3.1 Version 0.17.12

Version 0.17.12 incorporates the following changes from version 0.15.12.

A new solver for the steady-state heat equation was developed and implemented in FINIX [6]. The new solver decreases computation time in steady-state cases by at least 15%.

A new fission gas release model was implemented. The fission gas release model is presented in detail in section 5.1. As grain size is an important parameter in fission gas release, a grain growth model was implemented. Grain size is now reported in the Results structure for each pellet radial node.

Fuel pellet swelling due to solid and gaseous fission product accumulation and densification are now modeled with correlations. Solid fission product swelling is modeled with a correlation from MATPRO, and gaseous fission product swelling wither with a correlation from FRAPCON or a method connected to the fission gas release model. Densification is modeled with a correlation...
from FRAPCON. Densification changes the fractional density of the fuel, which is now reported in the Results structure for each pellet radial node.

Apart from time-independent plastic deformation, time-dependent plastic deformation (creep) is now also modeled. If the effective stress on the cladding exceeds the yield stress, the time-independent plastic deformation is calculated, otherwise the creep deformation is calculated. A bug from the previous version where plastic deformation could only occur outwards was corrected. Plastic deformation (time-independent and -dependent) can now occur also inwards. Another bug from the radial return algorithm was corrected, and the algorithm is now numerically more stable.

A radial power distribution model was implemented.

The fast neutron flux in and fluence of the cladding are now calculated with a simple correlation from the average power density in an axial segment. The proportionality factor can be changed in the Results structure.

Memory allocation in FINIX functions was improved. In previous versions, functions within the main iteration loop reserved their own memory on each function call. A new Workspace structure was implemented, for which memory is allocated before the calculation process. Significant decreases in computation time were obtained by this optimization: in the test case of IFA-329 rod bc, the computation time decreased by 45 % when 100 pellet radial and 50 cladding radial nodes were used. With a smaller number of nodes, the decrease in computation time is slightly less.

Power density and pellet and cladding densities are now saved in the Results structure. The values are now calculated in the same way in all functions that use them.

The gap conductance correlation from FRAPCON-4.0 was implemented alongside the previous FRAPCON gap conductance correlation. In the new correlation, one constant has a different value. The use of the FRAPCON-4.0 correlation leads to lower fuel centerline temperatures than either the FRAPTRAN or FRAPCON-3.4 correlations previously implemented in the code. The FRAPCON-4.0 correlation is set as the default.

The function naming scheme in FINIX was streamlined. All functions are now either special functions, such as structure constructors and destructors, or belong to a module which is part of the function’s name.

### 2.3.2 Version 0.15.12

Version 0.15.12 incorporates the following changes from version 0.15.6.

Time-independent plasticity of the cladding is modeled in FINIX version 0.15.12. The radial return method is implemented to solve the plasticity equations. The plastic deformation model is described in detail in section 4.3.3. PNNL stress-strain correlation is used to calculate yield stress.

A new data structure Cylindrical was implemented for storing results in each component in cylindrical coordinates. This is used to store various values of stresses and strains, for example.

The pellet axial strain is now taken from the pellet centerline, as this yields the maximum value of axial strain.

Material correlations for Zr1%Nb cladding used in VVER reactors are now implemented. Material-specific correlations for thermal conductivity, heat capacity, Young’s modulus, Meyer’s hardness, axial and diametral thermal expansion and yield stress are implemented.
Minor bug was fixed in the cladding mechanical model which caused the radial discretization to be converted to constant-distance scheme in the cladding.

A bug in the material density calculation was fixed. Previously the density was underestimated and this affected also the temperature calculations. As a result of the fix, predicted fuel centerline temperatures are higher by approximately 1% – 7%.

2.3.3 Version 0.15.6

Version 0.15.6 incorporates the following changes from version 0.13.9.

FINIX data structures have been completely redesigned. All the data FINIX requires or calculates is now stored in five structures. These structures hold the data describing the fuel rod, rod boundary conditions, FINIX simulation options, FINIX simulation results, and the data describing the simulated scenario. The old data arrays described in code documentation for version 0.13.9 are no longer available.

Version 0.15.6 introduces the ability to read input from FINIX and FRAPTRAN input files. Input files are still not necessarily needed in a coupled system, where the host code provides the boundary conditions for FINIX. However, the input files contain several templates that can be used as a starting point even in coupled-code simulations, if all necessary fuel performance input data is not available. If FINIX is run as a stand-alone code, the fuel rod characteristics, boundary conditions and model options should be provided through input files. FINIX no longer contains hard coded input.

FINIX version 0.15.6 allows the user to print new types of output files. These files include node-specific output files, a summary file, and a file showing the contents of all FINIX data structures.

Some bug fixes and minor changes have been done in version 0.15.6. An error in the cladding hoop stress equation (Eq. (48)) was corrected. The effect of this correction is described in section 9. Also, FINIX did not use the fast neutron fluence from the FRAPCON restart file previously, but this value is now used by FINIX.

2.3.4 Version 0.13.9

Version 0.13.9 incorporates the following changes from version 0.13.1.

In the interface, power density array has been replaced with linear power (per axial node) and radial power distribution (separately for each axial node) arrays. This change was necessary to conserve linear power in the axial node with the introduction of the relocation model. Because the relocation model can drastically change the dimensions of the pellet, using just a fixed power density does not conserve linear power over one time step.

Also in the interface, the params array was split into two arrays. The first one (params) only contains values that are not updated by FINIX. The second one (sresults, for scalar results) contains values that can be updated by FINIX. The previous results array was also renamed vresults (vector form results, for each axial node).

Radial relocation of the pellet is now modeled.

Several quantities have been added to improve FINIX’s simulation capabilities at accumulated burnup. These include pellet swelling and densification strains, cladding plastic strains, calculation of pressure from moles of gas instead of fill pressure, possibility to use He, Ar, Kr, Xe, H₂, N₂ and H₂O as fill gas. In FINIX 0.13.9 these values are not updated internally by FINIX, but can be given by the user to initialize FINIX of accumulated burnup.
Rod internal pressure calculation is now based on the gas molar content instead of fill pressure. The change was made to allow changes in the amount of fill gas that will be necessary when fission gas release models are added to FINIX. The fill pressure is still given as input.

Gap conductance correlation has been updated to include the above mentioned fill gases. Also, an option has been added to switch between FRAPCON and FRAPTRAN implementations of the gap conductance correlation. The FRAPTRAN correlation is used as a default (see Section 9).

A module for reading FRAPCON/FRAPTRAN restart files has been added. This can be used to initialize FINIX for accumulated burnup by using FRAPCON to provide the data from steady state irradiation.

A FINIX database of simulation and rod data used in the FINIX-0.13.9 validation [1] was created. The database is currently written inside the source code in files database.c and db_functions.c. The default rod parameters used in system setup that used to be in defaults.c in FINIX-0.13.9 were also moved to database.c.

The stability of the numerical iteration of the gap conductance in the transient and initial state solvers has been improved. The transient solver now searches for upper and lower bounds for the solution and, once found, switches to the Dekker method [7] from the secant method.

Default nodalization of the radial nodes has been changed to equal volume rings from equal radius rings.

Several auxiliary functions have been added, including functions to calculate burnup from power history, density of the fuel and cladding, averages over cross sectional areas, and so on.

Small bug fixes, including the correlations for cladding Meyer’s hardness, cladding thermal conductivity, cladding diametral thermal strain.

2.4 FINIX publications

In addition to the VTT reports, the following work related to FINIX development has been published:

3. Thermal model

3.1 The heat equation

The conduction of heat is described by the heat equation, where the temperature $T$ in general is a function of time $t$ and all three spacial coordinates. In a cylindrical fuel rod, a convenient choice for the coordinate system are the cylindrical coordinates, $r$, $\theta$ and $z$. In the present case, however, we make the simplifying assumption that within each axial slice, $T$ has no dependence on $z$ (by assuming the axial heat transfer to be negligible) and no dependence on $\theta$ (by assumed symmetry). With these assumptions, the heat equation takes the form

$$C_V(T) \frac{dT}{dt} - \frac{1}{r} \frac{\partial}{\partial r} \left[ \lambda(T) r \frac{\partial T}{\partial r} \right] - s(r) = 0. \quad (1)$$

Here $C_V$ is the volumetric heat capacity, $\lambda$ the thermal conductivity and $s$ the source term (thermal power line density). The temperature is a function of time $t$ and the radial coordinate $r$, $T = T(r, t)$. The solution of Eq. (1) is obtained in the fuel pellet and in the cladding by discretizing the equation with the finite element method (FEM) and by solving the system numerically (see Sec. 7.2.1 for transient heat equation).

The steady-state heat equation simplifies to

$$-\frac{1}{r} \frac{\partial}{\partial r} \left[ \lambda(T(r)) r \frac{\partial T}{\partial r} \right] - s(r) = 0. \quad (2)$$

The numerical solution of Eq. (2) is explained in detail in section 7.2.2.

The outer surface of the pellet and the inner surface of the cladding are subject to heat transfer boundary conditions

$$q(R_f) = -\lambda(T(r)) \frac{\partial T}{\partial r} \bigg|_{r=R_f} = h \left[ T(R_f) - T(R_{ci}) \right], \quad (3)$$

where $q(r)$ is the heat flux, $R_f$ is the fuel outer radius, $R_{ci}$ the cladding inner radius and the notation $|_{r=R_f}$ denotes evaluation of the preceding expression at $r = R_f$. The gap conductance
\( h \) is calculated using the model described in Sec. 3.3. The gap is assumed to have negligible heat capacity, and thus the conservation of energy implies that the heat flux across the inner surface of the cladding is given by

\[
q(R_{ci}) = \frac{R_f}{R_{ci}} q(R_f).
\]

(4)

At the outer surface of the cladding, the boundary condition can be set as constant temperature, constant heat flux or by using a heat transfer coefficient. A more thorough explanation is given in Sec. 7.2.1, where the numerical solution of the heat equation is explained. The remaining boundary condition is the zero heat flux at the inner surface of the pellet (at \( R_0 \)),

\[
q(0) = 0 \iff \frac{\partial T}{\partial r} \bigg|_{r=R_0} = 0.
\]

(5)

### 3.2 Plenum temperature

The model for the plenum gas temperature is derived by assuming that the gas within the plenum is well mixed and described by a single temperature, \( T_{plen} \). The gas exchanges heat with the surrounding walls, whose temperatures are taken as given. Furthermore, it is assumed that the heat capacity of the plenum gas is so small that one can neglect the term with the time derivative of \( T \). One therefore has the steady-state heat equation for the plenum gas,

\[
A_p h_p (T_p - T_{plen}) + A_c h_c (T_c - T_{plen}) = 0,
\]

(6)

which gives

\[
T_{plen} = \frac{A_p h_p T_p + A_c h_c T_c}{A_p h_p + A_c h_c}
\]

(7)

for the temperature of the plenum. Here \( A_p(A_c) \) is the area of the end of the fuel pellet (cladding inner surface) facing the plenum, \( T_p(T_c) \) the temperature of the pellet (cladding), and \( h_p(h_c) \) the heat transfer coefficient between the pellet (cladding) and the plenum gas. The areas are given by \( A_p = \pi R_f^2 \) and \( A_c = \pi R_{ci}^2 + 2 \pi l_p R_{ci} \), where \( l_p \) is the (axial) length of the plenum. The temperature of the end of the pellet is calculated as an area-weighted mean temperature (cf. Sec. 7.2). Since the cooling of the end of the pellet due to heat flux into the plenum is not taken into account in the 1D heat equation, this leads to slight over-estimation of the temperature \( T_p \). The temperature of the cladding is assumed to be equal to the coolant temperature, which in turn leads to slight under-estimation of the temperature \( T_c \). The uncertainties introduced in these approximation are not too severe, since the plenum affects the thermo-mechanical solution of the fuel rod only through its coupling to the gap pressure, not affecting the temperatures directly. In addition, solving the surface temperatures accurately would require 2D solution of the heat equations within the plenum, which would lead to undesirable increase in the computational intensity of the model.

The heat transfer coefficients are solved with a similar method as the one used in FRAPTRAN [15]. For the pellet-plenum heat transfer, the coefficient is

\[
h_p = \begin{cases} 
0.27 \lambda_{plen} \left( \frac{Gr Pr}{2R_{ci}} \right)^{0.25} & \text{for } Gr < 0, \\
0.54 \lambda_{plen} \left( \frac{Gr Pr}{2R_{ci}} \right)^{0.25} & \text{for } 0 \leq Gr \leq 2 \cdot 10^7, \\
0.14 \lambda_{plen} \left( \frac{Gr Pr}{2R_{ci}} \right)^{0.33} & \text{for } Gr > 2 \cdot 10^7,
\end{cases}
\]

(8)

where \( \lambda_{plen} \) is the thermal conductivity of the plenum gas, \( Pr \) is the Prandtl number and

\[
Gr = \frac{g (T_p/T_{plen} - 1) (2R_{ci})^3}{\nu^2}
\]

(9)
is the Grashof number. In the latter, \( g \) is the gravitational acceleration and \( \nu \) is the kinematic viscosity of the plenum gas.

For the cladding-plenum heat transfer coefficient, the corresponding equations are

\[
h_p = \begin{cases} 
0.55\lambda_{plen} \left( \frac{GrPr}{l_p} \right)^{0.25}, & \text{for } Gr \leq 1 \cdot 10^9, \\
0.021\lambda_{plen} \left( \frac{GrPr}{l_p} \right)^{0.4}, & \text{for } Gr > 1 \cdot 10^9,
\end{cases}
\]  

(10)

with

\[
Gr = \frac{g (T_c/T_{plen} - 1) l_p^3}{\nu^2}.
\]

(11)

The correlations for the Prandtl number and the kinematic viscosity are given in Sec. 6.4. The value for the heat conductivity \( \lambda_{plen} \) is not needed, as it is canceled from Eq. (7).

### 3.3 Gas gap conductance

The heat transfer in the gas gap is modelled with Eq. (3), with the heat transfer coefficient \( h \) given as a sum of three terms:

\[
h = h_{cond} + h_{rad} + h_{contact}.
\]

(12)

The first term corresponds to heat conduction across the gap, the second to radiation heat transfer between the pellet surface and the cladding inner surface, and the last one to heat transfer due to solid-solid contact of the pellet and the cladding. When the gas gap remains open, the last term is zero.

#### 3.3.1 Conduction through the gas

The term \( h_{cond} \) can be calculated from the heat equation in the gas gap. Assuming the heat capacity of the gas to be small and noting that there is no heat produced in the gap, the equation reduces to \( \left. \frac{\partial}{\partial r} \left( \lambda_{gap}(T) r \frac{\partial T}{\partial r} \right) \right|_{r=R_f} = 0 \). Integrating once with respect to \( r \) and applying \( \lambda_{gap} \left. \frac{\delta T}{\delta r} \right|_{r=R_f} = h_{cond}(T_{ci} - T_f) \) gives

\[
\lambda_{gap}(T) dT = h_{cond}(T_{ci} - T_f) \frac{dr}{r}.
\]

(13)

By integrating from \( T_f \) to \( T_{ci} \) and replacing the temperature-dependent heat conductivity with the average \( \tilde{\lambda}(T_{ci}, T_f) \) as \( \int_{T_f}^{T_{ci}} \lambda_{gap}(T) dT \equiv \tilde{\lambda}(T_{ci}, T_f)(T_{ci} - T_f) \), one obtains

\[
h_{cond} = \frac{1}{R_f \ln \left( 1 + d/R_f \right)}.
\]

(14)

where \( d = R_{ci} - R_f \) is the gap width. Since \( d \ll R_f \), the term \( \ln \left( 1 + d/R_f \right) \approx d/R_f \), which gives the form used in FRAPTRAN and FRAPCON:

\[
h_{cond} = \frac{\tilde{\lambda}(T_{ci}, T_f)}{d}.
\]

(15)

In practice, the average \( \tilde{\lambda}(T_{ci}, T_f) \) can be approximated by taking the average of the gap temperature, instead of the heat conductivity: \( \tilde{\lambda}(T_{ci}, T_f) \approx \lambda_{gap}(T_{gap}) \). The introduced error is of the order of a few percent, at most.
In FRAPTRAN and FRAPCON, an effective gap width $d_{\text{eff}}$ is used instead of the bare $d$. The same approach is taken also here. The effective gap width is given by the FRAPCON correlation [16, 17]

$$d_{\text{eff}} = e^{-0.00125P_{\text{contact}}}(\rho_f + \rho_c) + 1.8(g_f + g_c) - b + d,$$

where $P_{\text{contact}}$ is the contact pressure between the pellet and the cladding (in kg/cm$^2$, see Sec. 4.3.2), $\rho_f(\rho_c)$ is the surface roughness of the pellet (cladding) in meters. $g_f(g_c)$ is the temperature jump distance (in meters) at the pellet (cladding) surface. The constant $b = 1.397 \times 10^{-6}$ m. The sum of the temperature jump distances is calculated from

$$g_f + g_c = A\left(\frac{\lambda \sqrt{T}}{P}\right)\left(\frac{1}{\sum_i a_i f_i M_i^{-1/2}}\right),$$

where $\lambda$, $T$ and $P$ are the thermal conductivity, temperature and pressure of the gas in units of W/mK, K and Pa, respectively, and $a_i$, $f_i$ and $M_i$ are the thermal accommodation coefficients, mole fractions and molecular weights of the gas constituents. The coefficient $A$ is 0.7816 in the FRAPCON-3.4 correlation and 0.0137 in the FRAPCON-4.0 correlation.

FINIX also has an option to use the FRAPTRAN correlation for the effective gap width. In this case, the gap width is given by

$$d_{\text{eff}} = e^{-0.00125P_{\text{contact}}}(\rho_f + \rho_c) + 0.0316(g_f + g_c) + d \quad \text{(optional)}.$$  \hspace{1cm} (18)

The heat transfer coefficient $h_{\text{cond}}$ is then given as

$$h_{\text{cond}} = \frac{\lambda_{\text{eff}}}{d_{\text{eff}}},$$

where $d_{\text{eff}}$ is given by Eq. (16) and $\lambda_{\text{eff}}$ is calculated for the gas mixture of $n$ species as [18]

$$\lambda_{\text{eff}} = \sum_{i}^{n} \frac{\lambda_i x_i}{\sum_{j} (1 - \delta_{ij}) \psi_{ij} x_j}.$$  \hspace{1cm} (20)

Here $\lambda_i$ is the heat conductivity and $x_i$ the mole fraction of the species $i$, $\delta_{ij}$ the Kronecker delta and

$$\psi_{ij} = \psi_{ij}'\left(1 + 2.41\frac{(M_i - M_j)(M_i - 0.142M_j)}{(M_i + M_j)^2}\right),$$

$$\psi_{ij}' = \frac{1 + (\lambda_i/\lambda_j)^{1/2}(M_i/M_j)^{1/4}}{2^{3/2} (1 + M_i/M_j)^{1/2}},$$

where $M_i$ is the molecular weight of the species.

The heat conductivity of the gases (with the exception of steam) is of the form

$$\lambda_i = A_i T^{B_i},$$

with the coefficients given in Table 1.

For the water vapour (steam), the heat conductivity is given by [18]

$$\lambda_{H_2O} = 4.44 \cdot 10^{-6} T^{1.45} + 9.45 \cdot 10^{-5} (2.1668 P/T)^{1.3} \quad \text{(for } T > 973.15 \text{ K}),$$

$$\lambda_{H_2O} = P/T (-2.851 \cdot 10^{-6} + 9.424 \cdot 10^{-10} T - 6.005 \cdot 10^{-14} T^2) + 1.009 (P/T)^2/(T - 273.15)^{4.2} + 17.6 \cdot 10^{-3} + 5.87 \cdot 10^{-5} (T - 273.15) + 1.08 \cdot 10^{-7} (T - 273.15)^2 - 4.5 \cdot 10^{-11} (T - 273.15)^3 \quad \text{(for } T \leq 973.15 \text{ K}).$$

Here $T$ is in Kelvin and $P$ in Pascal.

3.3.2 Radiation across the gap

The radiation heat transfer coefficient is given by the gray body radiation formula

\[
h_{\text{rad}} = \frac{\sigma_{SB} T_f^4 - T_{cl}^4}{\frac{1}{\varepsilon_f} + \frac{R_f}{R_{cl}} \left( \frac{1}{\varepsilon_c} - 1 \right) \frac{T_f^4 - T_{cl}^4}{T_f^4}}\]

(26)

where \(\sigma_{SB}\) is the Stefan-Boltzmann constant and \(\varepsilon_f(\varepsilon_c)\) is the emissivity of the fuel outer surface (cladding inner surface). The emissivities used in FINIX are

\[\varepsilon_f = 0.78557 + 1.5263 \cdot 10^{-5} T_f,\]

(27)

where the temperature is in Kelvin, and

\[\varepsilon_c = 0.809.\]

(28)

The correlation for \(\varepsilon_f\) is the same as in FRAPTRAN, while the value for \(\varepsilon_c\) is the same as in the FEMAXI code [19]. The latter was chosen over the FRAPTRAN correlation, which requires knowledge of the cladding oxide thickness, and currently FINIX has no model for cladding oxidation. In FRAPTRAN, the value \(\varepsilon_c = 0.809\) would correspond to an effective oxide thickness of approximately 3.9 microns.

3.3.3 Contact between the pellet and cladding

The contact heat transfer coefficient \(h_{\text{contact}}\) is given by

\[
h_{\text{contact}} = \begin{cases} 
13.740 \frac{\lambda_m p_{\text{rel}}^{1/2}}{\rho_f^{-0.528} \sqrt{\rho_f^2 + \rho_c^2}} & \text{for } P_{\text{rel}} \leq 9 \cdot 10^{-6}, \\
0.041226 \frac{\lambda_m p_{\text{rel}}^{1/2}}{\rho_f^{-0.528} \sqrt{\rho_f^2 + \rho_c^2}} & \text{for } 9 \cdot 10^{-6} < P_{\text{rel}} \leq 0.003, \\
4579.5 \frac{\lambda_m p_{\text{rel}}^{1/2}}{\rho_f^{-0.528} \sqrt{\rho_f^2 + \rho_c^2}} & \text{for } 0.003 < P_{\text{rel}} \leq 0.0087, \\
39.846 \frac{\lambda_m p_{\text{rel}}^{1/2}}{\rho_f^{-0.528} \sqrt{\rho_f^2 + \rho_c^2}} & \text{for } P_{\text{rel}} > 0.0087,
\end{cases}
\]

(29)

where \(P_{\text{rel}} = P_{\text{contact}}/H\) is the relative ratio of the contact pressure and Meyer’s hardness \(H_m\) of the cladding (see Sec. 6.2.4). In addition, \(\lambda_m = 2 \lambda_f \lambda_c / (\lambda_f + \lambda_c)\) is the geometric mean of the fuel thermal conductivity \(\lambda_f\) and the cladding thermal conductivity \(\lambda_c\). The correlation of Eq. (29) is the same as in FRAPTRAN, with the numerical constants merged into one.
4. Mechanical model

4.1 Internal pressure

The internal pressure $P$ of the rod is calculated from the ideal gas equation of state, $PV = nRT$, where $V$ is the gas volume, $n$ the amount of substance of the gas, $R$ the ideal gas constant and $T$ the temperature. Assuming that pressure differences between the gap, plenum and central hole equalize immediately, the internal pressure is given by

$$P = \frac{nR}{V_{\text{plen}}/T_{\text{plen}} + \sum_k \left( V_{\text{cent},k}/T_{\text{cent},k} + V_{\text{gap},k}/T_{\text{gap},k} \right)}.$$

Here the plenum volume is

$$V_{\text{plen}} = \pi R_{cl}^2 I_p,$$

the central hole volume

$$V_{\text{cent},k} = \pi R_{0,k}^2 I_{f,k},$$

and the gap volume

$$V_{\text{gap},k} = \pi I_{f,k} \left( R_{cl,k}^2 - R_{f,k}^2 \right),$$

where $k$ is the index of the axial slice and $I_{f,k}$ is the axial length of the fuel and $R_{0,k}, R_{f,k}$ and $R_{cl,k}$ are the pellet inner radius, pellet outer radius and cladding inner radius, respectively, of the $k$:th axial slice.

4.2 Pellet mechanical model

The fuel pellet is assumed to have an infinite elastic modulus and no stress-induced deformations (the so-called rigid pellet model [15]). Thermal strain and radial relocation, swelling and densification of the fuel are taken into account with correlations. The correlation between the thermal strain and temperature is presented in Sec. 6.1.3, pellet relocation correlation in Sec. 6.1.4, pellet solid and gaseous swelling correlations in Sec. 6.1.5 and pellet densification correlation in Sec. 6.1.6. The radial displacement of the pellet outer surface is calculated by integrating the strains over the pellet radius. The axial strain is calculated using the temperature on the center of the pellet for the thermal strain, where the strain is largest. The details of the thermal strain calculation are explained in Sec. 7.4.1. Swelling and densification strains are also included for the axial strain, but pellet relocation strain is neglected.

4.3 Cladding mechanical model

The mechanical model of the cladding is similar to the FRACAS-I model used in both FRAPCON and FRAPTRAN [15, 16]. The cladding mechanical model is further divided into two distinct situations. The first model considers the case when the gap remains open, and the mechanical equilibrium is determined simultaneously with the calculation of the internal pressure. The second model is invoked when the gap is closed, and the equilibrium is determined by a no-slip condition between the pellet and the cladding. The calculation of the plastic strain increment proceeds similarly in the open gap and closed gap cases. If the effective stress on the cladding exceeds the yield stress, the time-independent plastic strain calculation is commenced. Otherwise the creep model is used.
### 4.3.1 Open gap model

First, we consider the open gap mechanical model. In this case, the displacement of the cladding inner surface depends on the internal pressure, which in turn is a function of the gap volume. Therefore, the mechanical equilibrium has to be determined simultaneously with the internal pressure calculation. In practice, the solution has to be found iteratively, since no closed form solution of the full set of equations is known. This numerical procedure is explained in Sec. 7.4.2. For the purposes of deriving the equations, we take the rod internal pressure $P$ as given and fixed.

The cladding model is based on the thin wall approximation, which implies constant stress, strain and temperature across the cladding radial direction. The temperature is taken as the average temperature of the cladding from the solution of the heat equation. In addition, the loading and deformation of the cladding is assumed axisymmetric, and bending strains and stresses are neglected.

Given the internal pressure $P$, the outside (coolant) pressure $P_o$, and the cladding inner and outer radii, $R_{cl}$ and $R_{co}$, the hoop stress $\sigma_\theta$ and the axial stress $\sigma_z$ are obtained as

$$
\sigma_\theta = \frac{R_{cl}P - R_{co}P_o}{R_{co} - R_{cl}},
$$

$$
\sigma_z = \frac{R_{cl}^2P - R_{co}^2P_o}{R_{co}^2 - R_{cl}^2}.
$$

When the stresses are known, the effective stress and the effective strain can be calculated in order to find out whether the yield stress has been exceeded. The effective stress is calculated as described in section 4.3.3. The effective strain is calculated as a sum of visco plastic, thermal and elastic strains. If the yield stress has been exceeded, a plastic strain increment is calculated as described in section 4.3.3.

The hoop, axial and radial strains are connected to the stresses through relations

$$
\epsilon_\theta = \frac{1}{E} (\sigma_\theta - \nu \sigma_z) + \epsilon_{\theta}^{th} + \epsilon_{\theta}^{pl} + \nu \epsilon_{\theta}^{pl} + \epsilon_{\theta}^{c} + \nu \epsilon_{\theta}^{c},
$$

$$
\epsilon_z = \frac{1}{E} (\sigma_z - \nu \sigma_\theta) + \epsilon_{z}^{th} + \epsilon_{z}^{pl} + \nu \epsilon_{z}^{pl} + \epsilon_{z}^{c} + \nu \epsilon_{z}^{c},
$$

$$
\epsilon_r = -\frac{\nu}{E} (\sigma_\theta + \sigma_z) + \epsilon_{r}^{th} + \epsilon_{r}^{pl} + \nu \epsilon_{r}^{pl} + \epsilon_{r}^{c} + \nu \epsilon_{r}^{c},
$$

Here $\epsilon_{\theta}^{th}$ are the cladding thermal strains (see Sec. 6.2.3), $\epsilon_{\theta}^{pl}$ the cladding plastic strains, $\epsilon_{\theta}^{c}$ the cladding plastic strain increments (zero if yield stress was not exceeded), $\epsilon_{\gamma}^{pl}$ the cladding creep strains, $\epsilon_{\gamma}^{c}$ the cladding creep strain increments, $E$ the Young’s modulus (Sec. 6.2.5) and $\nu$ the Poisson ratio (Sec. 6.2.6). The strains relate the dimensions of the cladding in the hot state to the dimensions in the cold state. The axial strain is essentially decoupled from the hoop and radial strains, so that the axial length of the slice is

$$
l_c = (1 + \epsilon_z)l_{c, \text{cold}}.
$$

where the subscript $k$ identifying the axial slice has been dropped for convenience [cf. Eq. (33)]. The corresponding relations for the cladding inner and outer radii can be derived from the change in the radius of the cladding midplane, $(R_{co} + R_{cl})/2 \equiv \bar{R} = (1 + \epsilon_\theta)R_{c, \text{cold}}$ and the
change in the cladding thickness, \( R_{co} - R_{ci} = (1 + \epsilon_r) (R_{co, cold} - R_{ci, cold}) \). The resulting expressions for \( R_{ci} \) and \( R_{co} \) are

\[
R_{ci} = R_{ci, cold} \left( 1 + \frac{1}{2} \epsilon_\theta + \frac{1}{2} \epsilon_r \right) + R_{co, cold} \left( \frac{1}{2} \epsilon_\theta - \frac{1}{2} \epsilon_r \right),
\]

(40)

\[
R_{co} = R_{ci, cold} \left( \frac{1}{2} \epsilon_\theta - \frac{1}{2} \epsilon_r \right) + R_{co, cold} \left( 1 + \frac{1}{2} \epsilon_\theta + \frac{1}{2} \epsilon_r \right).
\]

(41)

Equations (40) and (41) relate the radii to their cold-state values and the strains, thus completing the model.

The open gap model of Eqs. (34)–(41) is solved iteratively. This is because the values of \( R_{ci} \) and \( R_{co} \) are used to determine the stresses \( \sigma_\theta \) and \( \sigma_z \), which in turn are used to solve \( R_{ci} \) and \( R_{co} \).

### 4.3.2 Closed gap model

**Strong contact.** If the open gap model indicates that the inner surface of the cladding is in contact with the pellet, i.e., \( R_{ci} \leq R_f + \rho_f + \rho_c \), then the solution of the mechanical equilibrium proceeds with the closed gap model. For the closed gap model, one uses similar relations to the open gap model, albeit with different boundary conditions. Since the gap is closed, the internal gas pressure cannot be used as a boundary condition. Instead, the contact pressure \( P_{contact} \) between the pellet and the cladding remains to be determined. However, the inner radius of the cladding is fixed by the contact, so that

\[
R_{ci} = R_f + \rho_f + \rho_c.
\]

(42)

In addition, the axial strain of the cladding, \( \epsilon_z \), is determined by the no-slip condition at the pellet-cladding boundary. Any axial strain of the pellet that takes place after the gap has closed is added to the cladding axial strain. The axial strain of the cladding is therefore

\[
\epsilon_z = \epsilon_{z,0} + \epsilon^{fuel}_{z} - \epsilon^{fuel}_{z,0},
\]

(43)

where the additional subscript 0 indicates the strain just prior to gap closing.

For the closed gap, the cladding outer radius can be solved explicitly. After some algebraic manipulation, one gets

\[
R_{co} = \frac{1}{\sqrt{V}} \left( R_{co, cold} + R_{ci, cold} \right) - 2 \frac{R_{co, cold} R_{ci, cold}}{R_{co, cold} + R_{ci, cold}} R_{ci} + \frac{R_{co, cold}^2 - R_{ci, cold}^2}{R_{co, cold} + R_{ci, cold}}.
\]

\[
= \left[ \frac{1}{\sqrt{V}} \left( \epsilon_z + \epsilon_{\theta}^{th} + \epsilon_{\theta}^{pl} + \epsilon_{\theta}^{c} + \epsilon_{z}^{th} + \epsilon_{z}^{pl} + \epsilon_{z}^{c} + \epsilon_{r}^{th} + \epsilon_{r}^{pl} + \epsilon_{r}^{c} + \epsilon_{r}^{c} \right) \right]^{-1}
\]

(44)

\[
= \left( \frac{1}{\sqrt{V}} \left( \epsilon_z + \epsilon_{\theta}^{th} + \epsilon_{\theta}^{pl} + \epsilon_{\theta}^{c} + \epsilon_{z}^{th} + \epsilon_{z}^{pl} + \epsilon_{z}^{c} + \epsilon_{r}^{th} + \epsilon_{r}^{pl} + \epsilon_{r}^{c} + \epsilon_{r}^{c} \right) \right)^{-1}
\]

(45)

From \( R_{ci} \) and \( R_{co} \) one can then solve the hoop and radial strains using

\[
\epsilon_\theta = \frac{R_{co} + R_{ci}}{R_{co, cold} + R_{ci, cold}} - 1,
\]

(46)

\[
\epsilon_r = \frac{R_{co} - R_{ci}}{R_{co, cold} - R_{ci, cold}} - 1,
\]

(47)
Equations (46) and (47) are equivalent with Eqs. (36) and (38). The strains then give the stresses as
\[ \sigma_\theta = \frac{E}{1 + \nu} \left( (\epsilon_\theta - \epsilon_\theta^{pl} - \epsilon_\theta^{c} + \epsilon_\theta^{c}) - (\epsilon_r - \epsilon_r^{pl} + \epsilon_r^{c} + \epsilon_r^{c}) \right), \] (48)
\[ \sigma_z = \nu \sigma_\theta + E \left( \epsilon_z - \epsilon_z^{th} - \epsilon_z^{pl} - \epsilon_z^{c} + \epsilon_z^{c} \right), \] (49)

Finally, the contact pressure is calculated from
\[ P_{contact} = \frac{\sigma_\theta (R_{co} - R_{cl}) + P_o R_{co}}{R_{cl}}, \] (50)

If the effective stress (calculated as described in section 4.3.3) exceeds the yield stress, a plastic strain increment is calculated as described in section 4.3.3. After the plastic strain increment has been calculated, the total strains are calculated from Eqs. (46) and (47), the stresses and contact pressure updated and \( R_{co} \) calculated.

**Weak contact.** If the solution of the closed gap model with the strong contact assumptions gives an interfacial pressure that is lower than the internal gas pressure, \( P_{contact} < P \), then the gas can push the cladding and the pellet slightly apart, allowing them to slide against each other. In this situation, the no-slip condition in the axial direction no longer holds. Instead, the axial strain of the cladding adjusts until the contact pressure equals the internal rod pressure, and the cladding again becomes axially locked with the pellet. In the weak contact case, no more plastic deformation is calculated.

For the weak contact case, the contact pressure \( P_{contact} = P \). The cladding inner radius \( R_{cl} \) is given as for the strong contact case. The outer radius \( R_{co} \) can be solved from the implicit equation,
\[ R_{co}^3 \frac{1}{R_{co,cold} - R_{cl,cold}} + R_{co}^2 \left( -\frac{R_{cl}}{R_{co,cold} - R_{cl,cold}} - 1 - \epsilon_z^{th} - \epsilon_z^{pl} + \epsilon_z^{c} + \epsilon_z^{c} + \frac{2\nu}{E} P_o \right) \]
\[ + R_{co} \left( -\frac{R_{cl}^2}{R_{co,cold} - R_{cl,cold}} - \frac{\nu}{E} (P_o - P) \right) \]
\[ + \frac{R_{cl}^3}{R_{co,cold} - R_{cl,cold}} + \left( 1 + \epsilon_r^{th} + \epsilon_r^{pl} + \epsilon_r^{c} + \epsilon_r^{c} + \frac{2\nu}{E} P \right) R_{cl}^2 = 0, \] (51)
using Newton-Raphson iteration [7]. The stresses and strains can then be solved from
\[ \sigma_\theta = \frac{R_{cl} P_{contact} - R_{co} P_o}{R_{co} - R_{cl}}, \] (52)
\[ \sigma_z = \frac{R_{cl}^2 P_{contact} - R_{co}^2 P_o}{R_{co}^2 - R_{cl}^2}, \] (53)
\[ \epsilon_\theta = \frac{1}{E} (\sigma_\theta - \nu \sigma_z) + \epsilon_\theta^{th} + \epsilon_\theta^{pl} + \epsilon_\theta^{c} + \epsilon_\theta^{c}, \] (54)
\[ \epsilon_z = \frac{1}{E} (\sigma_z - \nu \sigma_\theta) + \epsilon_z^{th} + \epsilon_z^{pl} + \epsilon_z^{c} + \epsilon_z^{c}, \] (55)
\[ \epsilon_r = -\frac{\nu}{E} (\sigma_\theta + \sigma_z) + \epsilon_r^{th} + \epsilon_r^{pl} + \epsilon_r^{c} + \epsilon_r^{c}. \] (56)
In the closed gap model, since the inner radius $R_{c\ell}$ is fixed by the boundary condition, there is no need to iterate the solution with the solution of the internal pressure $P$ (irrespective of the strength of the contact).

### 4.3.3 Plastic deformation model

Only time-independent plasticity of the cladding is modeled in FINIX, and only infinitesimal strains are covered by the approach. The calculations of the increment in plastic strain proceed similarly in both the open gap and the closed gap, strong contact cases. The following assumptions are made in FINIX concerning cladding plasticity:

- The cladding behaves isotropically,
- the cladding is incompressible,
- the cladding follows the strain hardening hypothesis,
- the cladding yields according to the von Mises yield criterion,
- the cladding follows the Prandtl-Reuss flow rule.

The following discussion and definitions are based on Refs. [20] and [21]. The onset of yielding can be determined from a yield function. When the yield function has a value below zero, the cladding behaves elastically. When the yield function is zero, the cladding yields, and positive values are impossible. In FINIX, the von Mises yield function is used. The von Mises yield function, $f_{VM}$, for a strain-hardening material is as follows:

$$f_{VM} = \sigma_e - \sigma_Y(\varepsilon_e).$$  \hspace{1cm} (57)

The so-called yield surface is determined by $f_{VM} = 0$. In Eq. (57), $\sigma_Y$ is the yield stress, which is a function of effective strain, and $\sigma_e$ is the (von Mises) effective stress. The calculation of the yield stress is discussed in section 6.2.9. The effective stress (and analogously, strain) is defined as

$$\sigma_e = \sqrt{\frac{3}{2} \sum_i S_i S_i},$$  \hspace{1cm} (58)

$$\varepsilon_e = \sqrt{\frac{2}{3} \sum_i \varepsilon_i \varepsilon_i},$$  \hspace{1cm} (59)

where $S_i$ is the deviatoric stress and $\varepsilon_i$ the deviatoric strain, or

$$S_i = \sigma_i - \frac{Tr(\sigma)}{3} = \sigma_i - \rho_{hs},$$  \hspace{1cm} (60)

$$\varepsilon_i = \varepsilon_i - \frac{Tr(\varepsilon)}{3}.$$  \hspace{1cm} (61)

Here, $Tr(\sigma)$ is the trace of the (Cauchy) stress tensor $\sigma$, or the sum of the principal values of the tensor. The second term in the deviatoric stress equation is therefore equivalent to the hydrostatic pressure, $\rho_{hs}$. Note that in this discussion, only the principal values of stresses and strains are used, so $\sigma_i = \sigma_{ii}$, for example.
Using Hooke’s law (see Eqs. (36), (37) and (38)) and the definition of deviatoric stress and strain, the following relation between the deviatoric stress and strain can be found:

\[ \frac{D}{\text{uni}} = 2 \left( \frac{E}{2(1 + \nu)} \right) \frac{e}{\text{uni}} = 2Ge, \]  

(62)

where we have defined the shear modulus, \( G \). For effective stress and effective strain, a similar relationship can be found using their definitions and Eq. (62):

\[ \sigma_e = 3G\varepsilon_e. \]  

(63)

When stresses resulting in an effective stress greater than the yield stress is calculated to occur with the elastic solution, FINIX solves the increment in plastic strain by the radial return algorithm in order to return the stresses to the yield surface determined by Eq. (57). The radial return algorithm is an implicit integration algorithm, so all values of stress and strain refer to stresses and strains at the end of the time step. The effective stress in Eq. (57) can be decomposed into a effective trial stress and an effective plastic strain increment, \( d\varepsilon^p_e \), that returns the stress to the yield surface (see Ref. [21] for the derivation):

\[ \sigma_e = \sigma_{e,\text{trial}} - 3Gd\varepsilon^p_e. \]  

(64)

The effective trial stress can be calculated from the trial stress with Eq. (58). The trial stress components are calculated using the following equation (see Ref. [21] for the derivation):

\[ \sigma_{\text{trial},i} = \sigma_i + 2Gd\varepsilon^p_i. \]  

(65)

The plastic strain increment components, \( d\varepsilon^p_i \), are obtained from the Prandtl-Reuss flow rule, Eq. (67). Substituting Eq. (64) into Eq. (57), we can now solve for the effective plastic strain increment that satisfies the yield function:

\[ \sigma_{e,\text{trial}} - 3Gd\varepsilon^p_e - \sigma_Y(e^p_e) = 0. \]  

(66)

This is called the radial return method, which is widely used in solving the plasticity equations. The effective plastic strain increment is found from Eq. (66) by Newton-Raphson iteration. An initial guess of \( 1 \cdot 10^{-15} \) is used in FINIX. When the effective plastic strain increment is found, the individual components of the plastic strain increment are obtained from the Prandtl-Reuss flow rule:

\[ d\varepsilon^p_i = \frac{3}{2\sigma_e} \frac{s_i}{d\varepsilon^p_e}. \]  

(67)

With the knowledge of the plastic strain increment components, one may calculate the stresses at the end of the time step by solving for \( \sigma_i \) in Eq. (65). The new stresses and plastic strain increments are then used to calculate the total strains from Hooke’s law. In the open gap case, both the inner and outer radius of the cladding are updated with the new strains, but in the closed gap, strong contact case only the cladding outer radius is updated.

The increments in plastic strain are only added to the plastic strain after the solution for the time step has converged. It must be noted that the effective plastic strain must be treated separately from the plastic strains as the effective plastic strain depends on the past deformation and does
not decrease. The effective plastic strain is a sum of all the effective plastic strain increments
that have occurred in the past.

### 4.3.4 Creep model

The creep model of Limbäck and Andersson [22] or a model by Geelhood [23] can be used in FINIX. The models divide creep into primary and secondary creep, and are valid at normal operating temperatures. High-temperature creep is not modeled. In turn, secondary creep is further divided into thermal and irradiation creep. However, the implemented models differ in the selection of the driving force for primary creep, and their treatment of the time on the creep curve (see Eq. (68)). The differences are described in detail below.

Primary creep is assumed to be dependent on the secondary creep strain rate, \( \dot{\varepsilon}_s \). Using the conditions of the current time step, the secondary creep strain rate (see Sec. 6.2.8) is calculated. With this secondary strain rate, the saturated primary creep strain, \( \varepsilon_{p, sat} \), (see Sec. 6.2.7) is calculated. The primary creep strain is assumed to follow a function

\[
\varepsilon_{c,p} = \varepsilon_{p, sat} (1 - \exp( f(\dot{\varepsilon}_s) t)),
\]

for which the function \( f(\dot{\varepsilon}_s) \) is described in Sec. 6.2.7.

The primary creep strain increment during a time step is calculated by

\[
\Delta \varepsilon_{c,p} = \alpha( \varepsilon_{c,p}(t_1) - \varepsilon_{c,p}(t_0)),
\]

where \( \alpha \) is the direction of creep.

The secondary creep strain increment is calculated from the sum of the thermal and irradiation creep rates as

\[
\Delta \varepsilon_{c,s} = b ( \dot{\varepsilon}_{c,s,th} + \dot{\varepsilon}_{c,s,irr} ) dt,
\]

where the time step is given in hours and \( b \) is the direction of creep. The increments in creep strain are added to the total creep strain only after the solution has converged at the end of a time step.

**Limbäck-Andersson model**  The time and driving forces in the Limbäck-Andersson model as implemented in FINIX are as follows: If the creep curve changes, the virtual time on the creep curve is adjusted according to the strain hardening rule. A new virtual time at the new creep curve, corresponding to the same creep strain at the previous creep curve, is found by the bisection method. From the values of \( \varepsilon_{c,p} \) calculated with the conditions at the previous and the current time step, the limits of a bisection iteration are set: If the creep strain \( \varepsilon_{c,p} \) is larger at this time, the new virtual time can be found between 0 and \( t \). If the creep strain \( \varepsilon_{c,p} \) is smaller at this time, the new virtual time must be greater than \( t \). If the time calculated in this case becomes very large, primary creep strain has saturated. When the hoop stress is tensile, tensile virtual time is advanced and compressive virtual time is decreased, and vice versa when the hoop stress is compressive. Neither time is allowed to decrease below zero. The driving force for both the primary and secondary creep is \( \sigma_e \), and the direction for both is same:

\[
\alpha = b = \frac{|\sigma_h|}{\sigma_h}.
\]
Geelhood model  The time and driving forces in the Geelhood model are as follows [23]: The time $t$ input into Eq. (68) is initialized to zero after each significant stress change. When other conditions than effective stress change, the strain hardening rule is applied as described above for the original Limbäck-Andersson model. The significance limit is set at 5 MPa. The direction of primary creep is the direction of the last effective stress (see Eq. (58)) change, and the direction of secondary creep is the direction of the hoop stress. The directions $a$ and $b$ in the previous equations are then

$$ a = \frac{|\Delta \sigma_e|}{\sigma e}, \text{ and}$$

$$ b = \frac{|\sigma_n|}{\sigma h},$$

where $\Delta \sigma_e$ is the last significant effective stress change and $\sigma_n$ the hoop stress. In calculating the secondary creep rate for the primary creep curve, $\Delta \sigma_e$ is used instead of $\sigma_e$ as in the original Limbäck-Andersson model. For secondary creep, $\sigma_h$ is used, as in the original model.

4.3.5 Failure models

FINIX includes two simple criteria [24] for rod failure: the plastic instability criterion and the overstrain criterion. The plastic instability criterion predicts rod failure when true effective strain of the cladding exceeds 0.02 and simultaneously the true effective strain rate exceeds 0.0278 s$^{-1}$ (100 h$^{-1}$). The overstrain criterion predicts rod failure when the true effective strain exceeds 0.5. The plastic instability criterion seems to be conservative, but improves the numerical stability of FINIX in cases of high strains. For numerical stability, the strain rate input into the plastic instability criterion at any given time step is calculated as a weighted average between current and previous strain rates.

5. Other models

5.1 Fission gas release

5.1.1 Intragrannular gas behaviour

The intragranular behavior of the fission gases – diffusion in the uranium oxide lattice, formation of intragranular bubbles and the growth and diffusion of the bubbles – is described by the Forsberg-Massih model [25]. The four-term approximation of the integration kernel reported by Hermansson and Massih [26] is used. Resolution from the grain boundary due to irradiation is ignored in the implementation in FINIX.

The Forsberg-Massih model approximately solves the differential equation

$$ \frac{\partial C(r, t)}{\partial t} = D_{\text{eff}}(t) \Delta, C(r, t) + \beta(t) $$

(74)

with boundary conditions

$$ C(r, 0) = C(a, t) = 0, $$

(75)

where $C$ is the concentration of the gas, $\beta$ the fission gas production rate (see Sec. 6.3.1) and $D_{\text{eff}}$ the effective diffusion coefficient.
The effective diffusion coefficient is calculated from the gas atom diffusion coefficient in trap-free media and the bubble diffusion coefficient as

$$D_{\text{eff}} = \frac{b}{b + g}D_{\text{atom}} + \frac{g}{b + g}D_{\text{bubble}},$$  \hspace{1cm} (76)

where $b$ is the rate of irradiation-induced resolution of gas atoms, $g$ the trapping rate of gas atoms into intragranular bubbles, $D_{\text{atom}}$ is the gas atom diffusion coefficient (see Sec. 6.3.2) and $D_{\text{bubble}}$ is the bubble diffusion coefficient. The bubble diffusion coefficient is as reported by van Uffelen et al. [27]:

$$D_{\text{bubble}} = \frac{3}{4} \frac{V_{\text{gas}} D_{\text{vol}}}{\pi R_b^3},$$  \hspace{1cm} (77)

where $V_{\text{gas}}$ is the gas atom volume, $8.4756 \times 10^{-29}$ m$^3$, $R_b$ the intragranular bubble radius (see Sec. 6.3.3) and $D_{\text{vol}}$ the volume diffusion coefficient (see Sec. 6.3.4).

The rate of irradiation-induced bubble resolution is calculated as [28]

$$b = 3.03 \pi l F (R_b + d)^2,$$  \hspace{1cm} (78)

where $l$ is the fission fragment range, $6 \mu$m, $F$ the fission rate, $R_b$ the intragranular bubble radius and $d$ the fission fragment damage radius, $1$ nm.

The trapping rate of gas atoms into bubbles is calculated as [28]:

$$g = \frac{4 \pi R_b N_b D_{\text{atom}}}{N_A},$$  \hspace{1cm} (79)

where $R_b$ is the intragranular bubble radius (see Sec. 6.3.3), $N_b$ the intragranular bubble number density (see Sec. 6.3.5), $D_{\text{atom}}$ is the gas atom diffusion coefficient (see Sec. 6.3.2) and $N_A$ is the Avogadro constant.

The approximate solution to Eq. (74) is described in detail by Forsberg and Massih [25] and Hermansson and Massih [26]. The solution method is otherwise as reported by the authors, except for the different grain surface boundary condition as discussed before and the introduction of a grain boundary sweeping model from FRAPCON, where a portion of the gas is removed from the grain to the grain boundary due to grain growth. The following correction factor is applied to the intragranular gas concentration as calculated by the Forsberg-Massih algorithm:

$$f_s = \frac{a_i^3 - a_{i-1}^3}{a_{i-1}^3},$$  \hspace{1cm} (80)

where $a_i$ is the new grain size and $a_{i-1}$ the grain size on the previous time step.

### 5.1.2 Intergranular gas behaviour and release

Because resolution of gas from the grain boundary is neglected in FINIX, the intra- and intergranular models can be solved independently. The grain boundary gas concentration from the intragranular model is used by the intergranular model as is, and the evolution of grain boundary bubbles is computed.

Bubble size and density are determined by the influx of gas atoms to the boundary from inside the grain, the diffusion of vacancies at the grain boundary and the coalescence of grain boundary bubbles.
Bubble growth due to gas atom and vacancy absorption and emission is calculated using the flux of gas atoms from the intragranular model and assuming a van der Waals equation of state for the gas in the bubble. The vacancy absorption rate with these assumptions is

$$\frac{dN_v}{dt} = \frac{2\pi D_v \delta_g}{kTS} (p - p_{eq}), \quad (81)$$

where $N_v$ is the number of vacancies in a grain boundary bubble, $D_v$ the grain boundary vacancy diffusion coefficient (see Sec. 6.3.6), $\delta_g$ the diffusion layer thickness, set as $5 \cdot 10^{-10}$ m [29], $k$ the Boltzmann constant, $T$ the temperature and $S$ a function of fractional coverage,$F_c$, defined as

$$S = \frac{-(3 - F_c)(1 - F_c) - 2 \ln F_c}{4}. \quad (82)$$

The pressure of the bubble is calculated as

$$p = \frac{kT N_g}{\omega_v N_v}, \quad (83)$$

where $N_g$ is the number of gas atoms in a grain boundary bubble and $\omega_v$ the volume of an atomic vacancy in the bubble, set as $4.09 \cdot 10^{-29}$ m$^3$.

The equilibrium pressure $p_{eq}$ is calculated with the radius of the grain boundary bubbles, $R_{gb}$, and the surface tension of the bubbles, $\gamma$,

$$p_{eq} = \frac{2\gamma}{R_{gb}}. \quad (84)$$

The radius is calculated from the volume of the bubbles, given by

$$V_{gb} = \omega_g N_g + \omega_v N_v, \quad (85)$$

where $\omega_g$ is the volume of a gas atom. The volume of the bubbles is related to the radius of the bubbles by

$$R_{gb} = \frac{3V}{4\pi\phi}. \quad (86)$$

where $\phi$ is a factor relating the volume of a lenticular bubble to that of a sphere, given as a function of the bubble dihedral angle $\theta$, and the relation is as follows

$$\phi = 1 - \frac{3}{2} \cos \theta + \frac{1}{2} \cos^3 \theta. \quad (87)$$

Solving Eqs. (81), (83), (84) and 85) gives the number of vacancies. With the number of gas atoms, the change in bubble area due to absorption of gas atoms as vacancies, $dA_{gb,g}$ is obtained. The change in bubble density due to the coalescence of bubbles is given by

$$\frac{dN_{gb}}{dt} = -\frac{6N_{gb}^2}{3 + 4N_{gb}A_{gb}} \left( \frac{dA_{gb,g}}{dt} \right). \quad (88)$$

In the coalescence of bubbles, the total number of gas atoms and vacancies in the grain boundary bubbles is assumed to be conserved. The numbers of gas atoms and vacancies per bubble must then be updated as the number of bubbles has changed.
Finally, the bubble volume is calculated through Eq. (85) which is used to calculate the area of bubbles. These are used to calculate the fractional coverage, $F_c$, with the bubble number density:

$$ F_c = N_{gb}A_{gb}. \quad (89) $$

If the value of $F_c$ exceeds the threshold fractional coverage of 0.5, the excess gas is released so that $F_c = 0.5$ by adjusting the bubble area. In the gas release, the ratio of gas atoms to vacancies in bubbles is maintained.

The fill gas composition is updated after release. The released gases are thought to consist only of xenon and krypton. A Xe/Kr ratio of 6.275 is assumed, which is an average value for the fission of $^{235}\text{U}$.

5.2 Grain growth

The grain growth model in FINIX is that of Ainscough [30]. Grain growth is assumed to be dependent only on the temperature, and the grain size after a time step $dt$, $a_1$, is calculated from the grain size at the previous time step, $a_0$, as

$$ a_1 = a_0 + kdt \left( \frac{1}{a_0} - \frac{1}{a_{\text{lim}}} \right) \quad (90) $$

where $k$ is the rate constant of grain growth in $m^2 \cdot s^{-1}$, given as

$$ k = 1.456 \cdot 10^{-8} \exp \left( \frac{-2.674 \cdot 10^5}{RT} \right) \quad (91) $$

and $a_{\text{lim}}$ the limiting grain size in meters, given as

$$ a_{\text{lim}} = 2.23 \cdot 10^{-3} \exp \left( \frac{-7620}{T} \right) \quad (92) $$

The bracketed term in Eq. (90) is not allowed to be negative, so grain size can only increase.

The grain size (diameter) calculated by the model is the linear intercept average grain size (diameter), $d_{LI}$. The value used elsewhere in FINIX is the average grain size, $d_{\text{ave}}$, for which the following relationship has been established [31]:

$$ d_{\text{ave}} = 1.558d_{LI}. \quad (93) $$

Conversions between these values are done within the grain growth function.

5.3 Radial power distribution

The Transuranus Burnup Equations (TUBRNP) radial power distribution model by Lassmann et al. [32] is implemented in FINIX. The TUBRNP model does not calculate the correct radial power distribution in gadolinia-doped fuel.

The radial power distribution model calculates the boundary condition for the time step. Therefore a call to the function `finix_steady_state_radial_power_distribution()` is required before a call to the main FINIX solver function.

The local concentrations of actinides are obtained from the following group of differential equations:

$$ \frac{N_{U-235}(r)}{dB} = -\sigma_{a,U-235}N_{U-235}(r)A, \quad (94) $$
Table 2. Parameters of the radial form function, as in [17].

<table>
<thead>
<tr>
<th></th>
<th>LWR</th>
<th>HWR</th>

</table>

\[
\frac{N_{U-238}(r)}{dB} = -\sigma_{a,U-238} N_{ave,U-238} f(r) A,\quad (95)
\]

\[
\frac{N_{Pu-239}(r)}{dB} = -\sigma_{a,Pu-239} N_{Pu-239} f(r) A + \sigma_{c,U-238} N_{ave,U-238} f(r) A, \quad \text{and} \quad (96)
\]

\[
\frac{N_{Pu-j}(r)}{dB} = -\sigma_{a,Pu-j} N_{Pu-j} f(r) A + \sigma_{c,Pu-(j-1)} N_{Pu-(j-1)} f(r) A, \quad (97)
\]

where $\sigma_{a,i}$ are absorption cross sections of nuclide $i$, $j$ is from 240 to 242, $\sigma_{c,i}$ the capture cross sections of nuclide $i$, $B$ the burnup and $A$ is a normalization factor defined as

\[
A = 0.8815 \frac{\rho_{\text{fuel}}}{\sum_k \sigma_{l,k} N_{k,ave}}, \quad (98)
\]

and $f(r)$ a radial shape function defined as

\[
f(r) = 1 + p_1 \exp \left(-p_2 (r_{fo} - r)^{p_3}\right), \quad (99)
\]

where $r_{fo}$ is the pellet radius and $p_i$ empirical constants. The radii are input in millimeters. The cross sections used by FINIX are reported in section 6.5. The radial shape function is normalized so that

\[
2 \int_{r_{fi}}^{r_{fo}} f(r)r dr = 1, \quad (100)
\]

and the parameters $p_i$ are given separately for light and heavy water reactors as defined in table 2. The integral in Eq. (100) is calculated with Simpson’s rule.

The local non-normalized power density is calculated from

\[
q'_{\text{non-norm.}}(r) = \sum_k \sigma_{l,k} N_k \phi, \quad (101)
\]

where $\phi$ is the neutron flux. Solutions from diffusion theory are used to calculate a non-normalized value of $\phi$ through the following proportionality:

\[
\phi(r) \propto \begin{cases} 
I_0(\kappa r) & \text{for a solid cylinder, and} \\
I_0(\kappa r) + K_0(\kappa r) & \text{for a hollow cylinder,} 
\end{cases} \quad (102)
\]
where \( I_i \) are the modified Bessel functions of the first kind of order \( i \), and \( K_i \) the modified Bessel functions of the second kind of order \( i \). The modified Bessel functions are calculated as per [7]. \( \kappa \) is the inverse diffusion length, defined as

\[
\kappa = \sqrt{3 \sum_s \sum_k \sigma_{a,k} N_{ave,k}}
\]  
(103)

where \( \Sigma_s \) is the macroscopic scattering cross section and \( \sigma_{a,k} \) the absorption cross sections of nuclide \( k \). To obtain normalized power factors, the volume-average non-normalized power is calculated with \( q''/q''_{non-norm} \) and the power factors calculated by \( q''_{ave}/q''_{ave} \).

5.4 Fast neutron flux and fluence

The fast neutron flux and fluence are calculated from the power density of the fuel with a simple correlation, which yields an approximate value. Fast neutron flux is calculated as

\[
\phi = \alpha_\phi \frac{P_{ave}}{\rho_{%td} \rho_{td}},
\]
(104)

where \( P_{ave} \) is the average power density over the pellet in the axial node, \( \rho_{%td} \) the fractional density, \( \rho_{td} \) the theoretical density of the fuel and \( \alpha_\phi \) the factor relating the specific power to fast neutron flux. A default value of \( 2.29 \cdot 10^{19} \) is used for \( \alpha_\phi \). Fast neutron fluence is calculated from the flux as

\[
\Phi = \phi dt,
\]
(105)

where \( dt \) is the time step.

6. Material correlations

The material correlations used in FINIX have been mostly adopted from the MATPRO library [18] and the FRAPTRAN fuel performance code [15]. VVER correlations have mostly been adopted from Shestopalov et al. [33]. Typically, the correlations are taken ‘as is’. Since they have been thoroughly tested within other fuel performance codes, detailed study of their applicability was not considered necessary at this point. Their properties are discussed in, e.g., Refs. [18, 34].

6.1 Fuel properties

6.1.1 Specific heat

The fuel specific heat correlation is the same as in FRAPTRAN and MATPRO [15, 18]. The specific heat \( c_m \) is given as

\[
c_m = K_1 \frac{\Theta^2 \exp(\Theta/T)}{T^2 \left[ \exp(\Theta/T) - 1 \right]^2} + K_2 T + K_3 \frac{Y E_d}{2RT^2} \exp(-E_d/RT),
\]
(106)

where \( T \) is the temperature in Kelvin, \( R \) is the ideal gas constant (\( \approx 8.314 \) J/molK) and \( Y \) is the oxygen-to-metal ratio. For \( \text{UO}_2 \), the numerical values of the constants are \( K_1 = 296.7 \) J/kgK, \( K_2 = 0.0243 \) J/kgK\(^2\), \( K_3 = 8.745 \cdot 10^7 \) J/kg, \( \Theta = 535.285 \) K and \( E_d = 1.577 \cdot 10^5 \) J/mol.
6.1.2 Thermal conductivity

The FRAPTRAN correlation (see Ref. [18]) is used for the fuel thermal conductivity. The thermal conductivity \( \lambda \) is given by

\[
\lambda = 1.0789 \frac{d}{1 + 0.5(1 - d)} \lambda_{95},
\]

(107)

where \( \lambda_{95} \) is the thermal conductivity for UO\(_2\) at 95 % of the theoretical density, and \( d \) is the as-fabricated density of pellet as a fraction from the theoretical value. The correlation for \( \lambda_{95} \) is

\[
\lambda_{95} = \left[ A + \alpha \cdot \text{gad} + BT + f(Bu) + (1 - 0.9e^{-0.04Bu}) g(Bu)h(T) \right]^{-1} + \frac{E}{T^2} e^{-F/T}.
\]

(108)

Here \( \text{gad} \) is the gadolinia weight fraction, \( Bu \) is the burnup (GWD/MTU) and \( T \) is the temperature (K). The functions introduced in Eq. (108) are \( f(Bu) = 0.00187Bu, g(Bu) = 0.038Bu^{0.28} \) and \( h(T) = [1 + 396 \exp\left(-Q/T\right)]^{-1} \), with \( Q = 6380 \) K. The constants in Eq. (108) are \( A = 0.0452 \text{ mK/kW}, \alpha = 1.1599, B = 2.46 \cdot 10^{-4} \text{ m/W}, E = 3.5 \cdot 10^3 \text{ Wk/m} \) and \( F = 16361 \) K.

6.1.3 Thermal strain

The thermal expansion correlation for UO\(_2\) is taken from MATPRO/FRAPTRAN. The correlation is valid in the solid phase (below \( T \approx 3110 \)) of the fuel pellet, and gives zero strain at 300 K. The (linear) thermal strain is

\[
\epsilon_{th} = K_1 T - K_2 + K_3 e^{-Ed/k_BT},
\]

(109)

where \( k_B \) is the Boltzmann constant, \( K_1 = 9.8 \cdot 10^{-6} \) 1/K, \( K_2 = 2.94 \cdot 10^{-3} \), \( K_3 = 0.316 \) and \( E_d = 1.32 \cdot 10^{-19} \) J. Ref. [18] reports the value \( K_2 = 2.61 \cdot 10^{-3} \) for the second constant. However, it is easy to verify that \( \epsilon_{th}(T = 300 \text{ K}) \approx 0 \) is given by \( K_2 = 2.94 \cdot 10^{-3} \).

6.1.4 Radial pellet relocation

Cracking and radial relocation of the fuel pellet due to irradiation and thermal stresses is modeled using the FRAPCON correlation for the pellet radial cracking. Relocation is given as the fractional closure of the gap in relation of the as-fabricated gap \( G \) as

\[
\Delta G/G = \left\{ \begin{array}{ll}
0.3 + 0.1f(Bu), & \text{for } LHR < 20 \text{ kW/m}, \\
0.28 + g(LHR) + [0.12 + g(LHR)]f(Bu), & \text{for } 20 \text{ kW/m} < LHR < 40 \text{ kW/m}, \\
0.32 + 0.18f(Bu), & \text{for } LHR > 40 \text{ kW/m},
\end{array} \right.
\]

(110)

where \( f(Bu) = Bu/5 \) for \( Bu < 5 \) MWd/kgU and \( f(Bu) = 1 \) otherwise, and \( g(LHR) = 0.0025(LHR - 20) \), with the linear hear rate \( LHR \) given in kW/m and the burnup \( Bu \) in MWd/kgU.

Half of the radial relocation is considered permanent (hard) and half recoverable (soft). In FINIX, the total (soft + hard) relocation is only taken into account in determining the gap conductance, while only the hard relocation is considered in the mechanical model and in determining the reduction in free volume for the pressure calculation.
6.1.5 Pellet swelling

**Solid swelling**  Swelling of the fuel matrix due to solid fission product accumulation is modeled with the MATPRO/FRAPCON correlation. Linear swelling strain is calculated as

\[
\frac{\Delta l}{l} = \begin{cases} 
2.067 \cdot 10^{-4} Bu, & \text{for } Bu < 80 \text{ MWd} \cdot \text{kgU}^{-1}, \\
2.867 \cdot 10^{-4} Bu, & \text{for } Bu \geq 80 \text{ MWd} \cdot \text{kgU}^{-1}, 
\end{cases}
\]

(111)

**Gaseous swelling**  For gaseous swelling, two correlations can be used: The FRAPCON correlation or if the fission gas release model is being used, the Pastore et al. gaseous swelling model.

The temperature-dependence of the linear gaseous swelling strain from the FRAPCON correlation is as follows:

\[
\left( \frac{\Delta l}{l} \right)_T = \begin{cases} 
4.55 \cdot 10^{-5} T - 4.37 \cdot 10^{-2}, & \text{for } 960^\circ C \leq T \leq 1370^\circ C, \\
-4.05 \cdot 10^{-5} T + 7.40 \cdot 10^{-2}, & \text{for } 1370^\circ C < T \leq 1832^\circ C.
\end{cases}
\]

(112)

The value of \( \frac{\Delta l}{l} \) also depends on burnup as follows:

\[
\frac{\Delta l}{l} = \begin{cases} 
0.0, & \text{for } Bu < 40 \text{ MWd} \cdot \text{kgU}^{-1}, \\
\left( \frac{\Delta l}{l} \right)_{Bu=40.0} - 10.0, & \text{for } 40 \leq Bu \leq 50 \text{ MWd} \cdot \text{kgU}^{-1}, \\
\left( \frac{\Delta l}{l} \right)_T, & \text{for } Bu > 50 \text{ MWd} \cdot \text{kgU}^{-1},
\end{cases}
\]

(113)

The Pastore et al. gaseous swelling model [29] requires some parameters calculated by the fission gas release model, so it can only be used when the fission gas release model is on. The linear intragranular gaseous swelling is calculated as

\[
\frac{\Delta l}{l} = \frac{4}{9} \pi N_{ig} R_{ig}^3,
\]

(114)

where \( N_{ig} \) is the intragranular bubble number density, calculated using a correlation by White and Tucker [35]

\[
N_{ig} = \frac{1.52 \cdot 10^{27}}{T} - 3.3 \cdot 10^{23},
\]

(115)

and \( R_{ig} \) the intragranular bubble radius, which is calculated with a correlation by Massih and Forsberg [28]

\[
R_{ig} = 1.453 \cdot 10^{-10} \exp(1.023 \cdot 10^{-3} T).
\]

(116)

The linear intergranular gaseous swelling strain in the Pastore et al. model is calculated from

\[
\frac{\Delta l}{l} = \frac{1}{6} N_{gf} R_{SAV} \frac{4}{3} \pi \phi R_{gf}^3,
\]

(117)

where \( N_{gf} \) is the grain face bubble number density, \( R_{SAV} \) the surface-area-to-volume ratio, \( \phi \) a geometric factor relating the volume of a lenticular bubble to that of a sphere (see Eq. (87)), and \( R_{gf} \) is the radius of a grain face bubble. \( N_{gf} \) and \( R_{gf} \) are calculated by the fission gas release model.
6.1.6 Pellet densification

The densification is calculated from a model from MATPRO. The model is based on measured resintering density change, but in FINIX a default value for the resintering density change is used, 98.82 kg·m⁻³. First, the maximum possible density change is calculated as

\[
\left( \frac{\Delta l}{l} \right)_{\text{max}} = \begin{cases} 
-0.148230, & \text{for } T < 1000 \text{ K}, \\
-0.281637, & \text{for } T \geq 1000 \text{ K},
\end{cases}
\]

and then the linear densification strain is calculated from

\[
\frac{\Delta l}{l} = \left( \frac{\Delta l}{l} \right)_{\text{max}} + \exp (-3.0 (Bu + c)) + 2.0 \exp (-35.0 (Bu + c)).
\]

The parameter \( c \) is iterated to yield a densification strain of zero for fresh fuel.

6.2 Cladding properties

6.2.1 Specific heat

Zircaloy cladding specific heat (in J·kg⁻¹·K⁻¹) is given as a function of temperature in a tabulated form in Table 3. The data is adopted from Ref. [18]. Between 300 K and 1248 K, the temperature is calculated by linear interpolation from the values of Table 3, while for temperatures lower than 300 K and higher than 1248 K, the specific heat is assumed constant.

For Zr1%Nb cladding, the data is presented similarly in a tabulated form in Table 4. The data is adopted from Ref. [33]. Between 393 K and 1400 K, the temperature is calculated by linear interpolation from the values of Table 4, while for temperatures lower than 393 K and higher than 1400 K, the specific heat is assumed constant.

6.2.2 Thermal conductivity

The thermal conductivity of Zircaloy below 2098 K is given by the FRAPTRAN correlation

\[
\lambda = 7.51 + 2.09 \cdot 10^{-2} T - 1.45 \cdot 10^{-5} T^2 + 7.67 \cdot 10^{-9} T^3,
\]

Table 3. The specific heat capacity of the Zircaloy cladding [18]. The specific heat is assumed to have a constant value both below \( T = 300 \text{ K} \) and above \( T = 1248 \text{ K} \).

</table>

where the temperature $T$ is given in Kelvin and the conductivity $\lambda$ in W·m$^{-1}$K$^{-1}$ [18].

According to Shestopalov et al. [33], the thermal conductivity of Zr1%Nb cladding below 2133 K is given by

$$\lambda = 15.0636e^{0.4618\cdot10^{-3}T}.$$  \hfill (121)

For both Zircaloy cladding at temperatures higher than 2098 K and Zr1%Nb cladding at temperatures higher than 2133 K, the conductivity (in W·m$^{-1}$K$^{-1}$) is

$$\lambda = 36.0.$$  \hfill (122)

6.2.3 Thermal strain

The correlation for Zircaloy cladding thermal strain is based on the correlation used in FRAPTRAN. The FRAPTRAN formulae give non-zero strain at $T = 300$ K, which we assume be the cold reference state of the system. Thus, the constant term is adjusted to give zero strain at 300 K. The difference w.r.t. the FRAP correlations is less than $10^{-4}$.

The correlation is given separately for the axial and diametral strains (the strain is assumed to be isotropic on the plane perpendicular to the axial direction, hence the diametral strain is used for both the radial and hoop thermal strain). The correlation is given separately for the $\alpha$ and $\beta$ phases of zirconium and interpolated in the intermediate regime.

For $T \leq 1073$ K, the strains are

$$\varepsilon_{\text{axial}}^\alpha = -1.192 \cdot 10^{-4} + (T - 273.15) \cdot 4.441 \cdot 10^{-6},$$  \hfill (123)

$$\varepsilon_{\text{diametral}}^\alpha = -1.80459 \cdot 10^{-4} + (T - 273.15) \cdot 6.721 \cdot 10^{-6},$$  \hfill (124)

and for $T \geq 1273$ K

$$\varepsilon_{\text{axial}}^\beta = -8.3942 \cdot 10^{-3} + (T - 273.15) \cdot 9.70 \cdot 10^{-6},$$  \hfill (125)
\[ \varepsilon_{\text{diametral}}^\beta = -6.7432 \cdot 10^{-3} + (T - 273.15) \cdot 9.70 \cdot 10^{-6}. \]  

(126)

For the intermediate temperatures the strains are interpolated from the \( \alpha \) and \( \beta \) phase values so that for \( 1073 \text{ K} < T < 1273 \text{ K} \)

\[ \varepsilon_{\text{axial}}^{\alpha-\beta} = \frac{1273 \text{ K} - T}{200 \text{ K}} \varepsilon_{\text{axial}}^\alpha + \frac{T - 1073 \text{ K}}{200 \text{ K}} \varepsilon_{\text{axial}}^\beta \]  

(127)

\[ \varepsilon_{\text{diametral}}^{\alpha-\beta} = \frac{1273 \text{ K} - T}{200 \text{ K}} \varepsilon_{\text{diametral}}^\alpha + \frac{T - 1073 \text{ K}}{200 \text{ K}} \varepsilon_{\text{diametral}}^\beta \]  

(128)

The correlations for Zr1%Nb cladding thermal strains are provided by Shestopalov et al. [33]. The correlations give zero thermal strain at 300 K. In the correlations below, \( \Delta T = (T - 883.0) \). The correlations are given for five temperature intervals. Below 573 K, the strains are given by

\[ \varepsilon_{\text{axial}} = -0.128 \cdot 10^{-2} + 3.859 \cdot 10^{-6} T + 0.134 \cdot 10^{-3} T^2, \]  

(129)

\[ \varepsilon_{\text{diametral}} = -0.200 \cdot 10^{-2} + 5.654 \cdot 10^{-6} T + 0.334 \cdot 10^{-3} T^2, \]  

(130)

at temperatures above 573 K but below 883 K by

\[ \varepsilon_{\text{axial}} = 0.137 \cdot 10^{-2} + 5.4 \cdot 10^{-6} (T - 573.0), \]  

(131)

\[ \varepsilon_{\text{diametral}} = 0.334 \cdot 10^{-8} T^2 + 5.654 \cdot 10^{-6} T - 0.200 \cdot 10^{-2}, \]  

(132)

at temperatures above 883 K but below 1153 K by

\[ \varepsilon_{\text{axial}} = 3.047 \cdot 10^{-3} + 2.312 \cdot 10^{-8} \Delta T - 7.358 \cdot 10^{-8} \Delta T^2 + 1.721 \cdot 10^{-10} \Delta T^3, \]  

(133)

\[ \varepsilon_{\text{diametral}} = 5.598 \cdot 10^{-3} + 2.312 \cdot 10^{-8} \Delta T - 7.358 \cdot 10^{-8} \Delta T^2 + 1.721 \cdot 10^{-10} \Delta T^3, \]  

(134)

at temperatures above 1153 K but below 2133 K by

\[ \varepsilon_{\text{axial}} = 1.0765 \cdot 10^{-3} + 9.7 \cdot 10^{-6} (T - 1153.0), \]  

(135)

\[ \varepsilon_{\text{diametral}} = 3.628 \cdot 10^{-3} + 9.7 \cdot 10^{-6} (T - 1153.0), \]  

(136)

and finally at temperatures higher than 2133 K by

\[ \varepsilon_{\text{axial}} = 1.0582 \cdot 10^{-2}, \]  

(137)

\[ \varepsilon_{\text{diametral}} = 1.313 \cdot 10^{-2}. \]  

(138)

6.2.4 Meyer’s hardness

Meyer’s hardness \( H_M \) is used in the gap conductance model to determine the magnitude of the contact heat transfer coefficient. The following correlation is used for \( H_M \) of Zircaloy cladding (note the error in sign of last term in [18]):

\[ H_M = \exp [26.034 + T(-0.026394 + T(4.3502 \cdot 10^{-5} - 2.5621 \cdot 10^{-8} T))], \]  

(139)

where the dimension of \( H_M \) is \((\text{N} \cdot \text{m}^2)\). In addition, the lower limit of \( H_M \) of Zircaloy is set as \( 1.94 \cdot 10^8 \text{ N} \cdot \text{m}^2 \).
Meyer’s hardness for Zr1%Nb cladding is given by Shestopalov et al. [33] for temperatures below 800 K as

$$H_M = 2172.1 \cdot 10^6 - 10.7055 \cdot 10^6 T + 27650 T^2 - 32.78 T^3 + 0.01423 T^4,$$

(140)

and for temperatures over 800 K as

$$H_M = \exp(26.034 - 2.6394 \cdot 10^{-2} T + 4.3502 \cdot 10^{-5} T^2 - 2.5621 \cdot 10^{-8} T^3),$$

(141)

where the dimensions of $H_M$ is (N·m$^{-2}$). Additionally, a minimum hardness of 1·10$^5$ N·m$^{-2}$ is specified for Zr1%Nb cladding.

### 6.2.5 Young’s modulus

The Young’s modulus $E$ of Zircaloy cladding is given separately for the $\alpha$ and $\beta$ phases [18]. Below 1094 K, the correlation used is

$$E^\alpha = (1.088 \cdot 10^{11} - 5.475 \cdot 10^7 T + K_1 + K_2)/K_3,$$

(142)

with $T$ in Kelvin and $E$ in N·m$^{-2}$. The coefficient $K_1$, $K_2$ and $K_3$ are calculated from

$$K_1 = (6.61 \cdot 10^{11} + 5.912 \cdot 10^8 T)\Delta,$$

(143)

$$K_2 = -2.6 \cdot 10^{10} C,$$

(144)

$$K_3 = 0.88 + 0.12 e^{-\Phi/10^{25}}.$$

(145)

Here $\Delta$ is the average oxygen concentration minus the oxygen concentration of as-received cladding (kg oxygen/kg Zircaloy), $C$ is the cold work (dimensionless ratio or areas) and $\Phi$ is the fast neutron fluence (n·m$^{-2}$).

From 1239 K upwards the correlation is

$$E^\beta = 9.21 \cdot 10^{10} - 4.05 \cdot 10^7 T.$$

(146)

In the intermediate range (1094 K < $T$ < 1239 K), the value is interpolated as

$$E^{\alpha-\beta} = \frac{1239K - T}{(1239 - 1094)K}E^\alpha + \frac{T - 1094K}{(1239 - 1094)K}E^\beta.$$

(147)

The Young’s modulus correlation for Zr1%Nb cladding is as in FRAPTRAN-1.4 [18]. At temperatures below 1073 K, it is given by

$$E = 1.21 \cdot 10^{11} - 6.438 \cdot 10^7 T + 3.021 \cdot 10^{12} x_O,$$

(148)

where $x_O$ is the mass fraction of oxygen in the cladding. At temperatures above 1073 K, the Young’s modulus is given by

$$E = 9.129 \cdot 10^{10} - 4.5 \cdot 10^7 T.$$

(149)

A minimum of 1 Pa is specified.

### 6.2.6 Poisson’s ratio

The correlation for the Poisson’s ratio $\nu$ is taken from FRAPTRAN [18]:

$$\nu = 0.42628 - 5.556 \cdot 10^{-5} T.$$

(150)

The temperature $T$ is given in Kelvin, and $\nu$ is dimensionless. The same correlation is used for both Zircaloy and Zr1%Nb claddings.
Table 5. Parameters of the Limbäck-Andersson creep rate correlation for stress relief annealed (SRA) and recrystallized annealed (RXA) claddings. Some parameters are the same for both types of cladding. $\Phi$ is the fast neutron fluence.

</table>

6.2.7 Primary creep

Primary creep in the model used in FINIX is assumed to be dependent on the secondary creep strain rate. The correlation for saturated primary creep strain is calculated as [22]:

$$
\varepsilon_\rho^{\text{sat}} = 0.0216\varepsilon_s\left(2 - \tanh\left(35500\varepsilon_s\right)\right)^{2.05},
$$

(151)

where $\varepsilon_s$ is the secondary creep strain rate. Primary creep strain at a time $t$ is then calculated from

$$
\varepsilon_\rho = \varepsilon_\rho^{\text{sat}}\left(1 - \exp\left(-52\sqrt{\varepsilon_s t}\right)\right).
$$

(152)

6.2.8 Secondary creep

In the creep model used in FINIX, secondary creep is subdivided into thermal and irradiation creep. The thermal creep rate is given by [22]:

$$
\dot{\varepsilon}_{th} = \frac{AE}{T} \left(\sinh \left(\frac{a_i\sigma_{eff}}{E}\right)^n \exp\left(-\frac{Q}{RT}\right)\right),
$$

(153)

where $A$, $E$, $a_i$, $n$ and $Q$ are parameters of the creep equation. The irradiation creep rate is given by

$$
\dot{\varepsilon}_{irr} = C_0\Phi^{C_1}\sigma_{eff}^{C_2}f,
$$

(154)

where $C_i$ and $f$ are parameters of the creep correlation and $\phi$ is the fast neutron flux.

The parameters of the model are those reported by PNNL for stress relief annealed (SRA) and recrystallized annealed (RXA) Zircaloy claddings. The selection of the parameters is made based on the user-given cold work parameter: if it is nonzero, SRA parameters are used, and RXA otherwise. The parameters are reported in table 5. There are no creep correlation parameters for Zr1%Nb cladding implemented in FINIX.

6.2.9 Yield stress

The PNNL stress-strain correlation [36] is used in the calculation of the yield stress for Zircaloy and Zr1%Nb claddings. Parameters for the correlation are reported by Geelhood et al. [36] for
Zircaloy and by Shestopalov et al. [33] for Zr1%Nb cladding. The yield stress, $\sigma_Y$, correlation has the following form:

$$\sigma_Y = Ke^n\left(\frac{\dot{\varepsilon}}{10^{-3}}\right)^m$$

(155)

where $K$, $n$ and $m$ are the strength coefficient, strain hardening exponent and strain rate exponent, parameters fitted to experimental data, and $\dot{\varepsilon}$ the strain rate. To find the yield stress after an amount of plastic strain has been accumulated, one must take into account that the yield stress then occurs at the intersection of the yield stress curve, described by Eq. (155), and the elastic stress-strain line:

$$\sigma = E(\varepsilon - \varepsilon^{pl})$$

(156)

First setting $\sigma = \sigma_Y$ and solving for $\varepsilon$ in Eq. (156) and then substituting $\varepsilon$ in Eq. (155) yields an implicit equation for the yield stress, so the yield stress must be solved iteratively. A value of 34.5 MPa is used as an initial guess. Currently, a fixed value of $1 \cdot 10^{-5}$ is used for the strain rate when determining whether the yield stress has been exceeded and a plastic strain increment should be calculated. However, the strain rate is reported to have a small effect on the calculated yield stress [36].

The strain, $\varepsilon$, in the correlation is true strain, and the yield stress is true stress. In FINIX, engineering stress and strain are used, so before using this correlation the values of stress and strain are converted into true stress and strain. The relation between true and engineering (or nominal) stress and strain are as follows:

$$\varepsilon_{true} = \ln (\varepsilon + 1)$$

$$\sigma_{true} = \sigma (\varepsilon + 1)$$

(157)

The major difference between engineering and true strain is that true strain is additive, whereas engineering strain is not. However, with very small strains, the error from using engineering strains additively is small. In the plastic strain calculation, the calculation of the plastic strain increment is done using true strain and stress, and the results are returned to FINIX as engineering strain and stress. Also, care is taken to only compare true yield stress with the true effective stress or engineering yield stress with the engineering effective stress.

**Strength coefficient.** For Zircaloy, the strength coefficient, $K$, is subdivided into terms that are functions of temperature of the cladding, $T$, fast neutron fluence, $\Phi$, cold work, $CW$, and cladding type. The strength coefficient for Zircaloy is calculated as follows:

$$K = \frac{K_T(1 + K_{CW} + K_\Phi)}{K_{clad}}.$$ 

(158)

$K_{clad}$ depends on the type of Zircaloy, and for Zircaloy-2 it is 1.305 and for Zircaloy-4 it is 1.0. The temperature-dependent term $K_T$ is reported for four temperature intervals. At temperatures below 750 K, it is given by

$$K_T = 1.176 \cdot 10^9 + 4.549 \cdot 10^5 T - 3.282 \cdot 10^3 T^2 + 1.728T^3,$$

(159)
at temperatures over 750 K but below 1090 K by
\[ K_T = 2.523 \cdot 10^6 \exp \left( \frac{2.850 \cdot 10^6}{T^2} \right), \]  
(160)

at temperatures over 1090 K but below 1255 K by
\[ K_T = 1.841 \cdot 10^8 - 1.435 \cdot 10^5 T, \]  
(161)

and finally at temperatures over 1255 K but below 2100 K by
\[ K_T = 4.33 \cdot 10^{-7} - 6.685 \cdot 10^4 T + 37.579 T^2 - 7.330 \cdot 10^3 T^3. \]  
(162)

The fast neutron fluence dependent term is reported for three fluence intervals. At fluences below \(0.1 \cdot 10^{25} \frac{n}{m^2}\) it is given by
\[ K_\Phi = (-0.1464 + 1.464 \cdot 10^{-25} \Phi) \cdot \left(2.25e^{20CW} \min\left(1, e^{\frac{T-550}{10}}\right) + 1\right), \]  
(163)

at fluences above \(0.1 \cdot 10^{25} \frac{n}{m^2}\) but below \(2 \cdot 10^{25} \frac{n}{m^2}\) by
\[ K_\Phi = 2.928 \cdot 10^{-26} \Phi, \]  
(164)

and finally for fluences above \(2 \cdot 10^{25} \frac{n}{m^2}\) but below \(12 \cdot 10^{25} \frac{n}{m^2}\) by
\[ K_\Phi = 0.532 + 2.662 \cdot 10^{-27} \Phi. \]  
(165)

The cold work dependent term is simply
\[ K_{CW} = 0.546 CW, \text{ when } 0 < CW < 0.75. \]  
(166)

For Zr1\%Nb cladding, the strength coefficient is reported separately for irradiated and unirradiated cladding. In FINIX, if the fast neutron fluence is greater than zero, the irradiated cladding correlation is used. For unirradiated cladding, the strength coefficient is given for two temperature intervals. For the temperature range \(293 K < T < 797.9 K\) the strength coefficient is
\[ K = 898.371 \cdot 10^6 - 1.912 \cdot 10^6 + 2.025 \cdot 10^3 T^2 - 0.9637 T^3, \]  
(167)

and for the temperature range \(797.9 K < T < 1223 K\) it is
\[ K = 1.518 \cdot 10^{10} e^{-0.005607}. \]  
(168)

For irradiated cladding, the strength coefficient of Zr1\%Nb is reported for three temperature intervals. For temperatures above 293 K but below 763 K, it is given by
\[ K = 916.855 \cdot 10^6 - 0.605 \cdot 10^6 T - 247.482 T^2, \]  
(169)

at temperatures above 763 K but below 859.4 K by
\[ K = 4.913 \cdot 10^{11} e^{-0.009657}, \]  
(170)

and at temperatures above 859.4 K but below 1223 K by
\[ K = 1.518 \cdot 10^{10} e^{-0.005617}. \]  
(171)
Strain hardening exponent. For Zircaloy, the strain hardening exponent, \( n \), is subdivided into terms that are functions of temperature, fast neutron fluence and the cladding type. The strain hardening exponent is calculated as follows for Zircaloy:

\[
n = \frac{n_T n_\Phi}{n_{\text{clad}}}. \tag{172}
\]

\( n_{\text{clad}} \) depends on the type of Zircaloy, and for Zircaloy-2 it is 1.6 and for Zircaloy-4 it is 1.0. The temperature dependent term, \( n_T \), is given for four temperature intervals. At temperatures below 419.4 K it is

\[
n_T = 0.11405. \tag{173}
\]

At temperatures above 419.4 K but below 1099.0772 K, it is given by

\[
n_T = -9.490 \cdot 10^{-2} + 1.165 \cdot 10^{-3}T - 1.992 \cdot 10^{6}T^2 + 9.588 \cdot 10^{10}T^3, \tag{174}
\]

and at temperatures above 1099.0772 K but below 1600 K by

\[
n_T = -0.227 + 2.5 \cdot 10^{-4}T. \tag{175}
\]

At higher temperatures than 1600 K, it is

\[
n_T = 0.173. \tag{176}
\]

The fast neutron fluence dependent term, \( n_\Phi \), is given for three fluence intervals. For fluence below \( 0.1 \cdot 10^{25} \frac{n}{m^2} \), the term is given by

\[
n_\Phi = 1.321 + 0.48 \cdot 10^{-25} \Phi, \tag{177}
\]

while above \( 0.1 \cdot 10^{25} \frac{n}{m^2} \) but below \( 2 \cdot 10^{25} \frac{n}{m^2} \) it is given by

\[
n_\Phi = 1.369 + 0.096 \cdot 10^{-25} \Phi, \tag{178}
\]

and above \( 2 \cdot 10^{25} \frac{n}{m^2} \) but below \( 7.5 \cdot 10^{25} \frac{n}{m^2} \) by

\[
n_\Phi = 1.544 + 0.00873 \cdot 10^{-25} \Phi. \tag{179}
\]

At fluences higher than \( 7.5 \cdot 10^{25} \frac{n}{m^2} \), the fluence dependent term is

\[
n_\Phi = 1.609. \tag{180}
\]

For Zr1\%Nb cladding, the strain hardening exponent is reported separately for irradiated and unirradiated cladding. In FINIX, if the fast neutron fluence is greater than zero, the irradiated cladding correlation is used. For unirradiated cladding, the strain hardening exponent is given by:

\[
n = 0.0463 + 0.000198T - 3.315 \cdot 10^{-7}T^2 + 1.391 \cdot 10^{-10}T^3. \tag{181}
\]

The lower limit for validity of the unirradiated cladding correlation is 293 K, and the upper limit is 1223 K. For irradiated cladding the strain hardening exponent is given for three temperature intervals. At temperatures above 293 K but over 759 K, it is given by

\[
n = -0.126 + 0.00135T - 3.537 \cdot 10^{-6}T^2 + 3.735 \cdot 10^{-9}T^3, \tag{182}
\]

at temperatures above 759 K but below 879 K by

\[
n = -0.240 + 0.00284T - 8.226 \cdot 10^{-6}T^2 + 9.277 \cdot 10^{-9}T^3 - 3.588 \cdot 10^{-12}T^4, \tag{183}
\]

and at temperatures above 879 K but below 1223 K by

\[
n = 0.0463 + 0.000198T - 3.315 \cdot 10^{-7}T^2 + 1.391 \cdot 10^{-10}T^3. \tag{184}
\]
Strain rate exponent. For both Zircaloy and Zr1%Nb claddings, the strain rate exponent is only dependent on the temperature of the cladding. For Zircaloy, the strain rate exponent is given for three temperature intervals. Below 750 K, it is

\[ m = 0.015. \] \hspace{1cm} (185)

Between 750 K and 800 K, the strain rate exponent is given by

\[ m = -0.544 + 7.458 \times 10^{-4} T, \] \hspace{1cm} (186)

and at temperatures over 800 K, it is given by

\[ m = -0.207 - 3.241 \times 10^{-4} T. \] \hspace{1cm} (187)

For Zr1%Nb cladding the strain rate exponent is reported for three temperature intervals. Below 752.2 K but over 293 K it is given by

\[ m = 0.0228 - 3.448 \times 10^{-7} T, \] \hspace{1cm} (188)

at temperatures over 752.2 K but below 902.1 K by

\[ m = -2.535 + 0.00663 T - 5.303 \times 10^{-6} T^2 + 1.347 \times 10^{-9} T^3, \] \hspace{1cm} (189)

and finally at temperatures over 902.1 K but below 1223 K by

\[ m = -0.162 + 3.080 \times 10^{-4} T. \] \hspace{1cm} (190)

6.3 Fission gas release properties

6.3.1 Gas atom production rate

The gas atom production rate (in moles) in FINIX is calculated as per Massih and Forsberg [28]:

\[ \beta = 0.3017 \frac{\dot{F}}{N_A}, \] \hspace{1cm} (191)

where \( \dot{F} \) is the fission rate in units of \( \text{m}^3\text{s}^{-1} \) and \( N_A \) the Avogadro constant.

6.3.2 Gas atom diffusion coefficient

The gas atom diffusion coefficient in FINIX is as per Turnbull [37, 38]:

\[ D_{\text{atom}} = 7.6 \times 10^{-10} \exp\left(-\frac{3500.0}{T}\right) + 5.64 \times 10^{-25} \sqrt{\dot{F}} \exp\left(-\frac{13800.0}{T}\right) + 8.0 \times 10^{-40} \dot{F}, \] \hspace{1cm} (192)

where \( \dot{F} \) is the fission rate in units of \( \text{m}^3\text{s}^{-1} \).

6.3.3 Intragranular bubble radius

The intragranular bubble radius is calculated in FINIX as per White and Tucker [35]

\[ R_b = 5.0 \times 10^{-10} \left(1 + 106 \exp\left(-\frac{8691}{T}\right)\right), \] \hspace{1cm} (193)

where \( T \) is the temperature and \( R_b \) is in meters.
6.3.4 Volume diffusion coefficient

The volume diffusion coefficient is calculated in FINIX as per van Uffelen et al. [27]:

\[
D_{\text{vol}} = 3.0 \cdot 10^{-5} \exp\left(-\frac{7.22 \cdot 10^{-19}}{kT}\right).
\]

where \( T \) is the temperature and, \( k \) the Boltzmann constant.

6.3.5 Intragranular bubble number density

The intragranular bubble number density is calculated in FINIX as per White and Tucker [35]:

\[
N_b = \frac{1.52 \cdot 10^{27}}{T} - 3.3 \cdot 10^{23}.
\]

6.3.6 Grain boundary vacancy diffusion coefficient

The grain boundary vacancy diffusion coefficient is calculated in FINIX as [29]:

\[
D_v = 6.9 \cdot 10^{-4} \exp\left(-\frac{5.35 \cdot 10^{-19}}{kT}\right).
\]

6.4 Gas gap and plenum properties

The gas conductivity model and correlations are discussed in Section 3.3.

The plenum gas model in FINIX has not been updated to treat gases other than helium. The plenum gas is thus assumed to consist solely of helium. While this is a crude approximation, it only affects the plenum temperature through the heat transfer coefficients calculated for the pellet surface and the cladding facing the plenum. Since both are in any case in contact with the same gas and thermal equilibrium in the plenum is assumed, the error resulting from the approximation is manageable until correlations for the other species can be introduced. The correlations for helium are taken from Ref. [39]. Compared to the FRAPTRAN correlations, the numerical values are very similar.

The dynamic viscosity \( \mu \), density \( \rho \) and Prandtl number \( Pr \) are given by

\[
\mu = 3.674 \cdot 10^{-7}T^{0.7} \text{ (kg/ms)},
\]

\[
\rho = 48.14 \cdot 10^{-5} \frac{P}{T} \left[1 + 0.4446 \cdot 10^{-5} \frac{P}{T^{1.2}}\right] \text{ (kg/m}^3),
\]

\[
Pr = \frac{0.717}{1 + 1.123 \cdot 10^{-8}P}T^{-(0.01 - 1.42 \cdot 10^{-9}P)} \text{ (dimensionless)}.
\]

In the above, \( T \) is given in Kelvin and \( P \) in N·m\(^{-2}\).

The kinematic viscosity is given by \( \nu = \frac{\mu}{\rho} \).
6.5 Neutronics

6.5.1 Cross sections

The radial power distribution model uses microscopic fission and capture cross sections for some actinides and a macroscopic scattering cross section. The current radial power distribution is that of Lassmann et al. [32], and it covers the actinides $^{235}\text{U}$, $^{238}\text{U}$, $^{239}\text{Pu}$, $^{240}\text{Pu}$, $^{241}\text{Pu}$ and $^{242}\text{Pu}$.

The macroscopic scattering cross section is set to be 300 barns ($10^{-24}$ cm$^2$).

The microscopic cross sections used by FINIX are those used also in FRAPCON, and are reported in table 6. Cross sections are given for light water and heavy water reactors separately.

Table 6. Cross sections used by the radial power distribution model. Subscript f denotes fission cross section and c the capture cross section. Cross sections are reported in barns ($10^{-24}$ cm$^2$).

6.6 Coolant

FINIX has a rudimentary implementation of a thermal-hydraulic model for calculation of heat transfer coefficients from the cladding to the coolant. The correlations are valid below the critical heat flux (CHF), in the forced convection and nucleate boiling regime. The validity of the correlations is internally checked by calculating the critical heat flux from the EPRI-1 correlation [40], and by comparing with the computed heat flux. Currently, FINIX has no model to calculate changes in bulk coolant temperature. Therefore, the coolant temperature is taken as given by the user.

6.6.1 Heat transfer coefficient

The heat transfer coefficient $h$ is given as the sum of the heat transfer coefficients from the Dittus-Boelter correlation ($h_{DB}$) and the Thom correlation ($h_{Thom}$). The latter describes the additional convection in the nucleate boiling regime, and is zero if the cladding surface temperature is below the saturated coolant temperature, i.e., if $T_{co} < T_{sat}$.

The Dittus-Boelter correlation is given in British units as [16]

$$h_{DB} = \left[ (-5.1889 \cdot 10^{-5} + 6.5044 \cdot 10^{-8}T_w)T_w + (3.5796 \cdot 10^{-7} - 1.0337 \cdot 10^{-9}T_w)P_w + 3.2377 \cdot 10^{-2} \right] \phi_w^{0.8} D_e^{-0.2},$$ (200)
where \( T_w \) and \( P_w \) are the temperature and pressure of the coolant (assumed light water in the correlations), \( \phi_w \) is the coolant mass flux and \( D_e \) the hydraulic diameter,

\[
D_e = \begin{cases} 
\frac{2d^2-\pi R^2}{\pi R}, & \text{for square lattice}, \\
\sqrt{3d^2-2\pi R^2}/\pi R, & \text{for hexagonal lattice}, 
\end{cases}
\]  

(201)

with \( d \) the rod pitch. Although the correlation for \( h_{DB} \) is given in British units, the conversion to and from SI units is handled internally by the respective FINIX functions. The output from the calculation is therefore in units of W/m\(^2\)K.

The Thom correlation, also in British units, is [15]

\[
h_{\text{Thom}} = \left( \frac{e^{P_w/1260}}{0.072} \right) \left( \frac{T_{co} - T_{sat}}{T_{co} - T_w} \right)^2
\]

(202)

with \( T_{sat} \) given by the Frapcon correlation

\[
T_{sat} = \left[ \left( (0.4616716 \cdot 10^{-8}P_w - 0.4424529 \cdot 10^{-4})P_w + 0.19042968 \right)P_w + 394.03519 \right],
\]

(203)

where the pressure is in psia and temperature in °F. For \( T_{co} < T_{sat}, h_{\text{Thom}} = 0 \).

### 6.6.2 Critical heat flux

The critical heat flux is estimated from the EPRI correlation [40], which is valid for a wide range of experimental parameters. The correlation can be used to derive a criticality criterion for the heat flux. If the relation

\[
q_k > \frac{A - x_k}{C}
\]

(204)

is satisfied, then the heat flux \( q_k \) (in units of MBtu/hrft\(^2\)) at axial node \( k \) exceeds the CHF. Here \( x_k \) is the thermal equilibrium quality (the non-dimensional expression of coolant enthalpy),

\[
x_k = \frac{h_k - h_{sat}}{h_{vap}}
\]

(205)

where the bulk fluid enthalpy \( h_k \) is evaluated at the axial node \( k \), and the saturated liquid enthalpy, \( h_{sat} \), and the enthalpy of vaporization, \( h_{vap} \), are given by internal correlations. The coefficients \( A \) and \( C \) in Eq. (205) are given by

\[
A = 0.5328(P_w/P\text{crit})^{0.1212} \phi^{0.3040 - 0.3285(P_w/P\text{crit})},
\]

\[
C = 1.6151(P_w/P\text{crit})^{1.4066} \phi^{0.4843 - 2.0749(P_w/P\text{crit})},
\]

(206)

(207)

where the critical pressure \( P\text{crit} = 3208.2 \) psia and the coolant mass flux \( \phi \) is given in units of Mlbm/hrft\(^2\).

### 7. Numerical implementation

#### 7.1 General outline of the execution order

The FINIX calculation of the thermal and mechanical time evolution of the fuel rod proceeds in discrete time steps \( \delta t \). For each time step, the thermal and mechanical solutions are found by numerical iteration. The iteration process is schematically presented in Fig. 1. The iteration
consists of two main loops. The outer loop consists of solving the thermal properties of the fuel and the cladding, the gap conductance and the heat equation and plenum temperature. The second loop consists of solving the internal pressure and pellet and cladding deformations, and is situated within the outer thermal iteration loop. For the mechanical solution, the internal pressure is used as a convergence criterion, while for the outer loop, convergence of the gap conductivities for all axial nodes is required. In between, fission gas behavior is solved. On the algorithm level, the iteration is performed using the secant method, which is a method similar to the Newton-Raphson method, but where the function derivative is evaluated numerically instead of analytically. The method is described in detail in, e.g., Ref. [7].

The numerical methods used to solve the individual modules are described in the following Sections.

7.2 Thermal model

7.2.1 Transient heat equation

FEM discretization of the 1D transient heat equation

As was discussed in Section 3.1, the temperature in the pellet and cladding is solved in axial slices, in each of which the temperature $T$ is assumed independent of the axial and azimuthal coordinates $z$ and $\theta$. The heat equation then takes the form

$$C_V [T(r)] \frac{\partial T}{\partial t} - \frac{1}{r} \frac{\partial}{\partial r} \left[ \lambda [T(r)] r \frac{\partial T}{\partial r} \right] - s(r) = 0,$$

(208)

with $C_V$ denoting the volumetric heat capacity and $\lambda$ the conductivity. Note that neither the heat capacity nor conductivity is assumed constant w.r.t. the coordinate $r$.

The heat equation (208) is discretized with the Finite Element Method (FEM) [41]. The pellet is divided into $n_f - 1$ radial elements, with the $i$-th element comprising the volume between the nodes at $r = r_i$ and $r = r_{i+1}$. The first node is located at the inner surface of the pellet ($r_1 = R_0$), while the last node is at the pellet outer surface ($r_{n_f} = R_f$). The cladding is similarly divided into $n_c - 1$ elements and $n_c$ nodes, with the first cladding node at the cladding inner surface ($r_{n_f+1} = R_{ci}$) and the last at the outer surface ($r_{n_f+n_c} = R_{co}$).

The gas gap element (between nodes $n_f$ and $n_f + 1$) is handled through the gap conductance boundary conditions, as will be discussed below. In what follows, an element will refer to a general element, either within the pellet or in the cladding, unless otherwise indicated. For the pellet elements, the material parameters (conductivity, heat capacity) are be given by the correlations of Sec. 6.1, and for the cladding elements by the correlations of Sec. 6.2.

Discretization of one element

In the finite element method, the continuous equations are discretized first for each element. The global discretization of the whole system is then assembled from the discretized individual elements. For each element, the numerical solution provides the value of the temperature only at the location of the nodes. Within the element, the solution is approximated by shape functions, or basis functions. In the simplest case, the basis functions are linear, so that within the element the temperature $T$ is assumed to behave linearly as a function of $r$. The actual finite element equations are then derived by minimizing the residual (discretization error) between the original equations and the discretized equations. The minimization can be done with several different methods. A common choice is the Galerkin method, where the minimization is done by weighting the residual with the basis functions [41]. This is also the method we will use.
Figure 1. Flowchart depicting the logic and execution order of the main FINIX modules and the interface between FINIX and the host code. Computation of a new time step begins from the top and proceeds through the modules as indicated by the arrows. Convergence checks are made for the gap conductance in the thermal model, and for the internal pressure in the mechanical model. On the first round of iteration, the convergence is always considered to have failed, so that the full thermo-mechanical model is executed at least once.
The temperature inside the \( i \)th element is approximated with linear basis functions \( N_i \) and \( N_{i+1} \) so that

\[
T(r) \approx [N_i(r) \ N_{i+1}(r)] \begin{bmatrix} T_i \\ T_{i+1} \end{bmatrix},
\]

where the square brackets indicate row and column vectors, \( T_i \) is the temperature at the \( i \)th node, and

\[
N_i(r) = \frac{r_{i+1} - r}{r_{i+1} - r_i},
\]

\[
N_{i+1}(r) = \frac{r - r_i}{r_{i+1} - r_i}.
\]

For Eq. (208), the Galerkin method results in the matrix equation

\[
\begin{bmatrix} N_i(r) \\ N_{i+1}(r) \end{bmatrix} C_V(r) [N_i(r)N_{i+1}(r)] dV \frac{\partial}{\partial t} \begin{bmatrix} T_i \\ T_{i+1} \end{bmatrix} - \begin{bmatrix} \lambda_{i,i} \\ \lambda_{i+1,i} \end{bmatrix} \begin{bmatrix} T_i \\ T_{i+1} \end{bmatrix} - \int \begin{bmatrix} N_i(r) \\ N_{i+1}(r) \end{bmatrix} s(r) dV = \begin{bmatrix} 0 \\ 0 \end{bmatrix},
\]

where the matrix elements \( \lambda_{i,j} \) are

\[
\lambda_{i,j} = -2\pi\Delta z \int_{r_i}^{r_j} r\lambda(r) \frac{\partial N_i(r)}{\partial r} \frac{\partial N_j(r)}{\partial r} dr + 2\pi\Delta z \int_{r_i}^{r_j} r\lambda(r)N_i(r) \frac{\partial N_j(r)}{\partial r} - 2\pi\Delta z \int_{r_i}^{r_j} r\lambda(r)N_j(r) \frac{\partial N_i(r)}{\partial r},
\]

and the integral operator can be written as \( \int dV = 2\pi\Delta z \int_{r_i}^{r_{i+1}} r dr \), since the integrands have no axial or azimuthal dependence in the slice of thickness \( \Delta z \). We also linearize the heat capacity \( C_V \), conductivity \( \lambda \) and the source term \( s \) within the element, so that, given the values at the nodes \( i \) and \( i+1 \) (denoted by subscripts), we have

\[
C_V(r) \approx C_i + (C_{i+1} - C_i) \frac{r - r_i}{r_{i+1} - r_i},
\]

\[
\lambda(r) \approx \lambda_i + (\lambda_{i+1} - \lambda_i) \frac{r - r_i}{r_{i+1} - r_i},
\]

\[
s(r) \approx s_i + (s_{i+1} - s_i) \frac{r - r_i}{r_{i+1} - r_i},
\]

for \( r_i \leq r \leq r_{i+1} \).

Integration over the element gives the matrix equation

\[
(K_i + C_i) \begin{bmatrix} T_i^{k+1} \\ T_{i+1}^{k+1} \end{bmatrix} = C_i \begin{bmatrix} T_i^k \\ T_{i+1}^k \end{bmatrix} + f_i,
\]

where time derivative has also been discretized with the implicit Euler method. The superscript of \( T \) indicates the time step of the time-discretized temperature, so that \( T^k \equiv T(r = r_i, t = k\delta t) \), where \( \delta t \) is the time step. The implicit Euler method remains unconditionally stable with all values of \( \delta t \) [41, 42]. The matrices in Eq. (217) are defined as follows:

\[
K_i = \frac{\lambda_i(2r_i + r_{i+1}) + \lambda_{i+1}(r_i + 2r_{i+1})}{6(r_{i+1} + r_i)} \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix},
\]

\[
c_i = \frac{r_{i+1} - r_i}{60\delta t} \begin{bmatrix} c_i(12r_i + 3r_{i+1}) + c_{i+1}(3r_i + 2r_{i+1}) & c_i(3r_i + 2r_{i+1}) + c_{i+1}(2r_i + 3r_{i+1}) \\ c_i(3r_i + 2r_{i+1}) + c_{i+1}(2r_i + 3r_{i+1}) & c_i(2r_i + 3r_{i+1}) + c_{i+1}(3r_i + 12r_{i+1}) \end{bmatrix},
\]

(218)

(219)
The second term in the vector $f_i$ is determined by the boundary conditions of the element, with $q_i$ the heat flux over the surface at $r = r_i$. The boundary conditions will be discussed in more detail below.

The gas gap element

For $i = \{1, 2, \ldots, n_f - 1, n_f + 1, n_f + 2, \ldots, n_f + n_c\}$, the element discretization is given by the $2 \times 2$ matrices derived in the previous Section. For the gas gap, i.e., the $n_f$:th element, the matrices are derived from the gas gap conductance model described in Sec. 3.3. Given the heat transfer coefficient $h$, the matrix $K_{nf}$ is

$$K_{nf} = \begin{bmatrix} hr_{nf} & -hr_{nf} \\ -hr_{nf} & hr_{nf} \end{bmatrix}.$$  \hfill (221)

There is no power generated in the gap, and the specific heat of the gas is assumed negligible. Hence, $C_{nf} = 0$ and $f_{nf} = 0$.

Global matrices

The global matrices for the whole system are assembled from the $2 \times 2$ element matrices by taking the sum node by node. The result is an $(n_f + n_c) \times (n_f + n_c)$ tridiagonal matrix. For brevity, we introduce a shorthand notation of the element matrices:

$$K_i \equiv \begin{bmatrix} K_{ii}^{(11)} & K_{ii}^{(12)} \\ K_{ii}^{(21)} & K_{ii}^{(22)} \end{bmatrix}, \quad C_i \equiv \begin{bmatrix} C_{i}^{(11)} & C_{i}^{(12)} \\ C_{i}^{(21)} & C_{i}^{(22)} \end{bmatrix}. \hfill (222)$$

Then, the global matrices are of the tridiagonal form

$$K = \begin{bmatrix} D_1 & U_1 & 0 \\ L_1 & D_2 & U_2 \\ & L_2 & D_3 \\ & & \ddots & \ddots & \ddots \\ & & & L_{n-2} & D_{n-1} & U_{n-1} \\ & & & & L_{n-1} & D_n \end{bmatrix},$$  \hfill (223)

where $n = n_f + n_c$ is the total number of nodes. The diagonal (D), upper diagonal (U) and lower diagonal (L) elements are given as

$$D_i = K_{ii}^{(11)} + K_{i-1}^{(22)} \quad \text{(for } 2 \leq i \leq n - 1\text{); } D_1 = K_{11}^{(11)}; \quad D_n = K_{n-1}^{(22)},$$ \hfill (224)

$$U_i = K_{i}^{(12)} \quad \text{(for } 1 \leq i \leq n - 1\text{),} \hfill (225)$$

$$L_i = K_{i}^{(21)} \quad \text{(for } 1 \leq i \leq n - 1\text{).} \hfill (226)$$

The matrix $C$ is assembled in a similar fashion, with the elements of the matrices $K_i$ replaced with the elements of $C_i$. 

$$f_i = \frac{r_{i+1} - r_i}{12} \left[ \frac{s_i(3r_i + r_{i+1}) + s_{i+1}(r_i + r_{i+1})}{s_i(r_i + r_{i+1}) + s_{i+1}(r_i + 3r_{i+1})} \right] + \left[ -r_i q_i \right].$$  \hfill (220)
The load vector is given as

\[
\mathbf{f} = \begin{bmatrix}
  f_1^{(1)} \\
  f_1^{(2)} + f_2^{(1)} \\
  f_2^{(2)} + f_3^{(1)} \\
  \vdots \\
  f_{n-2}^{(1)} + f_{n-1}^{(2)} \\
  f_{n-1}^{(2)} 
\end{bmatrix},
\]  

(227)

where \( f_i^{(1)} \) and \( f_i^{(2)} \) are the two components of \( f_i \):

\[
f_i \equiv \begin{bmatrix}
  f_i^{(1)} \\
  f_i^{(2)}
\end{bmatrix}.
\]  

(228)

Finally, the global matrix equation for the complete system is

\[
(K + C)\mathbf{T}^{k+1} = CT^k + \mathbf{f},
\]  

(229)

where the vector \( \mathbf{T}^k \) contains the temperatures at the \( k \)-th time step:

\[
\mathbf{T}^k \equiv \begin{bmatrix}
  T_1^k \\
  T_2^k \\
  \vdots \\
  T_n^k
\end{bmatrix}.
\]  

(230)

**Time discretization**

Implicit time discretization of the heat equation is implied in Eq. (229). The time discretization follows the standard implicit finite difference discretization (see, e.g., Ref. [42]), which remains unconditionally stable for all time steps \( \delta t \). The implicit formulation means that to calculate the temperature at time \( t = (k+1)\delta t \), the temperature-dependent terms of the heat equation are evaluated at the same point in time, at \( t = (k+1)\delta t \). For constant (non-temperature-dependent) material properties, it is possible to solve the one-dimensional implicit time-discretized matrix equation, Eq. (229), without iteration. However, since the material correlations depend on temperature, and cannot in general be linearized, it is necessary to iterate the solution of \( \mathbf{T}^{k+1} \), until the temperature converges. This is part of the iteration procedure described above in Sec. 7.1.

**Boundary conditions**

The boundary conditions affect the discretization of the elements at the center of the pellet and at the outer surface of the cladding. For the first element, the flux through the first node is set to zero, i.e., \( q_1 = 0 \) in Eq. (220). For the cladding outer surface, several alternative boundary conditions can be used.

*Dirichlet boundary condition.* For a fixed surface temperature, \( T(R_{co}) = T_{surf} \), the appropriate boundary condition is enforced by setting \( L_n = D_n = 0 \) for \( C \), \( L_n = 0 \) and \( D_n = 1 \) for \( K \), and \( f_{n-1}^{(2)} = T_{surf} \) in the load vector \( \mathbf{f} \). This is equivalent with the the equation \( T_n^{k+1} = T_{surf} \).

*Neumann boundary condition.* If the heat flux across the cladding outer surface is fixed, then one only needs to assign \( q_n \), the desired value in \( \mathbf{f} \).

*Robin boundary condition.* The heat flux can also be given as a function of the bulk temperature of the coolant, \( T_{coolant} \), and the heat transfer coefficient \( h_{co} \) so that \( q_n = h_{co} [T_n - T_{coolant}] \).
In this case, the last element of $f$ is $f_{n-1}^{(2)} = r_n h_{co} T_{\text{coolant}}$, and the remaining $r_n h_{co}$ is added to the last diagonal element $D_n$ in the matrix $K$.

In the case of the Robin boundary condition, the heat transfer coefficients can be computed from internal correlations (see Sec. 6.6) or, they be given by the user.

**Solution of the matrix equations**

The resulting matrix equation for the vector $\mathbf{T}^{k+1}$, Eq. (229), can be solved non-iteratively with the tridiagonal matrix algorithm, which a variant of the standard Gaussian elimination method. The algorithm is a standard numerical method, and its details are not explained here. The interested reader is referred to Chapter 2 of Ref. [7].

Although the heat equation itself can be solved non-iteratively, the dependence of the material properties, gap conductance and the pellet and cladding mechanical solution on the temperature requires iteration of the full thermo-mechanical solution. The scheme is described in more detail above, in Sec. 7.1.

### 7.2.2 Steady-state heat equation

**Discretization of the 1D steady-state heat equation**

For the steady state solver, we shall linearize the thermal conductivity and the power density inside the elements as is done with the transient solution in order to model the same distributions with both solvers.

If we consider the steady state form of the 1D heat equation

$$-rac{1}{r} \frac{\partial}{\partial r} \left[ \lambda(T(r)) r \frac{\partial T}{\partial r} \right] - s(r) = 0,$$

and write the linearization of the thermal conductivity and heat source as

$$a_q r + b_q = q_i + (q_{i+1} - q_i) \frac{r - r_i}{r_{i+1} - r_i},$$

with

$$a_q = \frac{q_{i+1} - q_i}{r_{i+1} - r_i},$$

$$b_q = q_i - (q_{i+1} - q_i) \frac{r_i}{r_{i+1} - r_i},$$

we can write the equation in a single element as

$$-rac{1}{r} \frac{\partial}{\partial r} \left[ (a_{\lambda} r + b_{\lambda}) r \frac{\partial T}{\partial r} \right] = a_s r + b_s,$$

Now we can work towards an analytic solution for the element inner node temperature $T_i$. 
Nonzero \( a \) and \( b \)

We’ll first assume that \( a_\lambda \neq 0 \) and \( b_\lambda \neq 0 \) and handle the exceptions later:

\[
-\frac{d}{dr} \left[ (a_\lambda r + b_\lambda) \frac{dT}{dr} \right] = a_s r^2 + b_s r + (a_\lambda r + b_\lambda) \frac{dT}{dr} = \frac{a_s}{3} r^3 + \frac{b_s}{2} r^2 + C_0
\]

Now we can integrate from \( r_i \) to \( r_{i+1} \) and from \( T_i \) to \( T_{i+1} \)

\[
- \int_{T_i}^{T_{i+1}} dT = \int_{r_i}^{r_{i+1}} \frac{a_s}{3a_\lambda} \left[ 3b_s a_\lambda - 2b_\lambda a_s \right] \frac{dr}{6a_\lambda^2} - \frac{3b_\lambda b_s a_\lambda - 2b_\lambda^2 a_s}{6a_\lambda^2 (a_\lambda r + b_\lambda)}
\]

We know that the thermal conductivity is positive throughout the integration interval, i.e.,

\[ a_\lambda r + b_\lambda > 0, \]

giving

\[
T_i - T_{i+1} = \frac{a_s}{6a_\lambda} \left( r_{i+1}^2 - r_i^2 \right) + \frac{3b_s a_\lambda - 2b_\lambda a_s}{6a_\lambda^2} (r_{i+1} - r_i)
\]

\[
- \frac{3b_\lambda b_s a_\lambda - 2b_\lambda^2 a_s}{6a_\lambda^3} \log \frac{a_\lambda r_{i+1} + b_\lambda}{a_\lambda r_i + b_\lambda}
\]

\[
+ \frac{C_0}{b_\lambda} \log \frac{r_{i+1}}{r_i} - \frac{C_0}{b_\lambda} \log \frac{a_\lambda r_{i+1} + b_\lambda}{a_\lambda r_i + b_\lambda}
\]

We can simplify the expression by substituting in the nodal thermal conductivity

\[ a_\lambda r_n + b_\lambda = \lambda_n \]

to get

\[
T_i - T_{i+1} = \frac{a_s}{6a_\lambda} \left( r_{i+1}^2 - r_i^2 \right) + \frac{3b_s a_\lambda - 2b_\lambda a_s}{6a_\lambda^2} (r_{i+1} - r_i)
\]

\[
- \frac{3b_\lambda b_s a_\lambda - 2b_\lambda^2 a_s}{6a_\lambda^3} \log \frac{\lambda_{i+1}}{\lambda_i}
\]

\[
+ \frac{C_0}{b_\lambda} \log \frac{r_{i+1}}{r_i} - \frac{C_0}{b_\lambda} \log \frac{\lambda_{i+1}}{\lambda_i}
\]

We see that if \( r_i = 0 \) we must have \( C_0 = 0 \). In other cases \( C_0 \) can be determined using the heat flux equation written at \( r = r_i \)

\[
q''(r_i) = (-\lambda(r) \nabla T(r))_{r=r_i} = \frac{P(r < r_i)}{2\pi r_i \Delta z} \hat{e}_r
\]
The equation states that the heat flux $q''$ at $r_i$ is equal to the power generated inside the cylindrical surface at $r = r_i$ divided by the surface area. This assumes steady state in heat transfer and generation as well as no axial heat transfer in the fuel. Taking the gradient of the one-dimensional temperature field gives

$$\left( -\lambda(r) \frac{\partial T}{\partial r} \right)_{r=r_i} \hat{e}_r = \frac{P(r < r_i)}{2\pi r_i \Delta z} \hat{e}_r. \quad (244)$$

We can substitute the derivative of the temperature using Eq. 238 to get

$$\frac{a_s}{3} r_i^3 + \frac{b_s}{2} r_i^2 + C_0 = \frac{P(r < r_i)}{2\pi r_i \Delta z} \quad (245)$$

$$\frac{a_s}{3} r_i^3 + \frac{b_s}{2} r_i^2 + C_0 = \frac{P(r < r_i)}{2\pi r_i \Delta z} \quad (246)$$

$$\frac{a_s}{3} r_i^3 + \frac{b_s}{2} r_i^2 + C_0 = \frac{P(r < r_i)}{2\pi r_i \Delta z} \quad (247)$$

Solving for $C_0$ yields

$$C_0 = \frac{P(r < r_i)}{2\pi \Delta z} - \frac{a_s}{3} r_i^3 - \frac{b_s}{2} r_i^2, \quad (248)$$

where the power term can be written as a multiple of the average linear power at regions $r < r_i$ and the height of the axial segment

$$P(r < r_i) = q'(r < r_i) \Delta z = \sum_{j=0}^{j=m-1} \int_{r_j}^{r_{j+1}} \alpha_s r + b_s dA \Delta z. \quad (249)$$

$$P(r < r_i) = \sum_{j=0}^{j=m-1} \int_{r_j}^{r_{j+1}} (\alpha_s r + b_s) 2\pi r d r \Delta z. \quad (250)$$

Finally we'll obtain an expression for $C_0$

$$C_0 = \sum_{j=0}^{j=m-1} \left[ \frac{a_s}{3} (r_{j+1}^3 - r_j^3) + \frac{b_s}{2} (r_{j+1}^2 - r_j^2) \right] - \frac{a_s}{3} r_i^3 - \frac{b_s}{2} r_i^2, (r_i \neq 0) \quad (251)$$

The value of $C_0$ depends only on the power distribution and the node radial coordinates.

**Nonzero $b$, zero $a$**

For the case where $\alpha _\lambda = 0$ we have a constant heat conductivity in the element. The solution of the heat equation is somewhat simplified:

$$-\frac{\partial}{\partial r} \left[ b_\lambda r \frac{\partial T}{\partial r} \right] = a_s r^2 + b_s r \quad (252)$$

$$-b_\lambda r \frac{\partial T}{\partial r} = \frac{a_s}{3} r^3 + \frac{b_s}{2} r^2 + C_0 \quad (253)$$

$$\frac{\partial T}{\partial r} = \frac{a_s}{3 b_\lambda} r^2 - \frac{b_s}{2 b_\lambda} r + \frac{C_0}{b_\lambda} \quad (254)$$

$$T_i - T_{i+1} = \frac{a_s}{9 b_\lambda} (r_{i+1}^3 - r_i^3) + \frac{b_s}{4 b_\lambda} (r_{i+1}^2 - r_i^2) + \frac{C_0}{b_\lambda} \log \frac{r_{i+1}}{r_i} \quad (255)$$

The constant $C_0$ has the same value as in the case with nonzero $\alpha _\lambda$ and $b_\lambda$. 
Nonzero a, zero b

For the case where $b_\lambda = 0$, the solution of the heat equation is again simplified:

$$\frac{\partial}{\partial r} \left[ a_\lambda r^2 \frac{\partial T}{\partial r} \right] = a_s r^2 + b_s r$$

$$-a_\lambda r^2 \frac{\partial T}{\partial r} = \frac{a_s}{3} r^3 + \frac{b_s}{2} r^2 + C_0$$

$$-\frac{\partial T}{\partial r} = \frac{a_s}{3a_\lambda} r + \frac{b_s}{2a_\lambda} + \frac{C_0}{a_\lambda r^2}$$

$$T_i - T_{i+1} = \frac{a_s}{6a_\lambda} (r_{i+1}^2 - r_i^2) + \frac{b_s}{2a_\lambda} (r_{i+1} - r_i) - \frac{C_0}{a_\lambda} \left( \frac{1}{r_{i+1}} - \frac{1}{r_i} \right)$$

Again, the constant $C_0$ is determined with Eq. 251.

Gas gap and cladding outer surface

Now we can use equations 242, 255 and 259 to determine the inner temperature for each element based on the outer temperature of the element, the linearized thermal conductivity in the element and the linearized power density distribution in the pellet. Since there are two elements whose outer temperature is not the inner temperature of the following element, namely the pellet surface element and the cladding outer surface element, we'll need additional relations to obtain the outer temperatures for these two elements.

In the gas gap we'll use the gas gap heat transfer coefficient ($h_{gap}$) calculated by FINIX to obtain the temperature difference across the gap:

$$(T_{fo} - T_{ci}) h_{gap} = q''_{fo}.$$  \hspace{1cm} (260)

The heat flux at the pellet outer surface is calculated simply as

$$q''_{fo} = \frac{q'}{2\pi r_{fo}},$$  \hspace{1cm} (261)

where $q'$ is the axial zone linear heat rate and $r_{co}$ is the pellet outer radius. The pellet surface temperature is then simply

$$T_{fo} = T_{ci} + \frac{q'}{2\pi r_{fo} h_{gap}}.$$  \hspace{1cm} (262)

The cladding outer surface may be given as a boundary condition. In the case, where the cladding outer surface temperature is not given as a boundary condition, we'll utilize the (user given) bulk coolant temperature ($T_{cool}$) and the heat transfer coefficient between the cladding and the coolant ($h_{cool}$) either given by user or calculated by FINIX:

$$(T_{cool} - T_{cool}) h_{cool} = q''_{co}.$$  \hspace{1cm} (263)
The heat flux at the cladding outer surface is calculated simply as

$$q''_{co} = \frac{q'}{2\pi r_{co}},$$  \quad (264)

where \(q'\) is the axial zone linear heat rate and \(r_{co}\) is the cladding outer radius. The cladding surface temperature is then simply

$$T_{co} = T_{cool} + \frac{q'}{2\pi r_{co} h_{cool}}.$$ \quad (265)

### Assembling the matrix equation

Based on the derivations done in the previous section we can assemble a matrix equation for the temperatures at the nodes. The coefficient matrix will have ones on the diagonal and minus ones on the first superdiagonal:

$$
\begin{bmatrix}
1 & -1 & 0 & 0 & \ldots & 0 & 0 \\
0 & 1 & -1 & 0 & \ldots & 0 & 0 \\
0 & 0 & 1 & -1 & \ldots & 0 & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
0 & 0 & 0 & 0 & \ldots & 1 & -1 \\
0 & 0 & 0 & 0 & \ldots & 0 & 1
\end{bmatrix}
\begin{bmatrix}
T_1 \\
T_2 \\
T_3 \\
\vdots \\
T_{n_f+n_c-1} \\
T_{n_f+n_c}
\end{bmatrix}
= 
\begin{bmatrix}
l_1 \\
l_2 \\
l_3 \\
\vdots \\
l_{n_f+n_c-1} \\
l_{n_f+n_c}
\end{bmatrix} \quad (266)
$$

The matrix equation can be solved by calculating the constants on the RHS and using backwards substitution.

The constants on the RHS are as follows:

**Elements in fuel pellet.** For \(l_i, i \in (0, \ldots, n_f - 1)\), we’ll use the solutions from equations 242, 255 and 259. In the case with \(a_\lambda \neq 0\) and \(b_\lambda \neq 0\) we have

$$l_i = \frac{a_s}{6a_\lambda} \left( r_{i+1}^2 - r_i^2 \right) + \frac{3b_s a_\lambda - 2b_\lambda a_s}{6a_\lambda^2} \left( r_{i+1} - r_i \right)$$

$$- \frac{3b_\lambda b_s a_\lambda - 2b_\lambda^2 a_s}{6a_\lambda^2} \log \frac{\lambda_{i+1}}{\lambda_i}$$

$$+ \frac{C_0}{b_\lambda} \log \frac{r_{i+1}}{r_i} - \frac{C_0}{b_\lambda} \log \frac{\lambda_{i+1}}{\lambda_i}. \quad (267)$$

For the case with \(a_\lambda = 0\) and \(b_\lambda \neq 0\) we have

$$l_i = \frac{a_s}{9b_\lambda} \left( r_{i+1}^3 - r_i^3 \right) + \frac{b_s}{4b_\lambda} \left( r_{i+1}^2 - r_i^2 \right) + \frac{C_0}{b_\lambda} \log \frac{r_{i+1}}{r_i} \quad (268)$$

and for the case with \(a_\lambda \neq 0\) and \(b_\lambda = 0\) we have

$$l_i = \frac{a_s}{6a_\lambda} \left( r_{i+1}^2 - r_i^2 \right) + \frac{b_s}{2a_\lambda} \left( r_{i+1} - r_i \right) - \frac{C_0}{a_\lambda} \left( \frac{1}{r_{i+1}} - \frac{1}{r_i} \right). \quad (269)$$
In all of the cases $C_0$ is either calculated using Eq. 251 or set to zero in the case of $r_i = 0$. One should note that $C_0$ has to be calculated separately for each element.

Gas gap element. For $d_{n_f}$ we’ll use the equation 262 to get

$$l_{n_f} = \frac{q'}{2\pi r_{fo} h_{gap}}.$$  \hfill (270)

Elements in cladding. For the cladding elements (i.e., $l_i, i \in (n_f + 1, \ldots, n_f + n_c)$), the constants on the RHS are calculated similar to pellet elements, barring the fact that the power distribution is zero in the element. Equations 267–269 can be simplified. In the case with $a_\lambda \neq 0$ and $b_\lambda \neq 0$

$$l_i = \frac{C_0}{b_\lambda} \log \frac{r_{i+1}}{r_i} - \frac{C_0}{b_\lambda} \log \frac{\lambda_{i+1}}{\lambda_i}.$$  \hfill (271)

For the case with $a_\lambda = 0$ and $b_\lambda \neq 0$ we have

$$l_i = \frac{C_0}{b_\lambda} \log \frac{r_{i+1}}{r_i}$$  \hfill (272)

and for the case with $a_\lambda \neq 0$ and $b_\lambda = 0$ we have

$$l_i = -\frac{C_0}{a_\lambda} \left( \frac{1}{r_{i+1}} - \frac{1}{r_i} \right).$$  \hfill (273)

Again, $C_0$ is calculated for each element using Eq. 251.

Cladding outer surface node. For the cladding outer surface we have, depending on the boundary condition, either

$$l_{n_f+n_c} = T_{co}$$  \hfill (274)

if the cladding outer surface $T_{co}$ is given as a boundary condition or

$$l_{n_f+n_c} = T_{cool} + \frac{q'}{2\pi r_{co} h_{cool}}$$  \hfill (275)

in the case of other boundary conditions.

### 7.3 Plenum temperature

The plenum temperature model described in Sec. 6.4 can be solved self-consistently for fixed plenum pressure and cladding and pellet surface temperatures. However, since the properties of the fill gas and thereby the heat transfer coefficients depend on the temperature, the equations do not have a closed form solution. Instead, the solution is found iteratively with the secant method [7]. The area-averaged temperature $T_0 = (A_p T_p + A_c T_c)/(A_p + A_c)$ is used as the initial guess. Typically, the iteration requires two steps or less to converge within the numerical tolerance.
7.4 Mechanical model

7.4.1 Rigid pellet model

The primary assumption of the rigid pellet approximation is that the pellet is rigid (hard) enough to be completely non-deformable under external stresses. Thus, the displacement of the pellet nodes and the outer surface can be calculated directly from the strain correlations, without iteration.

7.4.2 Cladding model

The employed cladding mechanical model depends on the type of contact between the pellet and the cladding. In principle, iteration of the mechanical solution with internal pressure is only necessary when the gap remains open; if the gap is closed, the gap volume is fixed and therefore does not affect the pressure. However, the model typically consists of several axial nodes, and the pressure is function of the displacements in all of those nodes. In some of the nodes, the gap may remain open while in others it is closed (due to, e.g., nonuniform axial power distribution). If the gap remains open even in some of the nodes, the internal pressure has to be solved iteratively. This iteration process then changes the boundary conditions in the closed gap model, which has to be re-solved. Therefore, even the closed gap models are solved several times because of the iteration of the mechanical solution of the full rod. Note that the plastic strain increments calculated on each iteration are only saved to the total plastic strains after the whole solution has converged (at the end of the time step).

In practice, the iteration is performed by first calculating an initial guess for the pressure (using the displacements from, e.g., previous time step), then solving the mechanical model for each axial node independently with fixed pressure, and finally re-calculating the pressure with updated displacements. The process is repeated, using the secant method to predict the pressure, until the internal pressure converges. Optionally, one can also use either the bisection or false position methods for the internal pressure prediction through an option implemented in the source code.

7.5 Other models

7.5.1 Fission gas release

The fission gas release model is connected to the internal pressure calculation through the gas mole amount and the thermal model through the fill gas composition.

On each iteration, a gas mole amount increment is calculated, and it is added to the gas mole amount only on convergence. During the iteration, the gas mole amount on each iteration is thought to consist of the gas mole amount plus its increment, which varies between iterations.

The fill gas composition is calculated for the sum of the gas mole amount and its increment on each iteration, and the composition on the previous time step is saved in FINIX internal data structures between time steps.
8. Usage instructions

8.1 General description

The FINIX fuel behavior model and interface is designed to work primarily as a subprogram within a larger simulation code, to provide or replace the existing fuel performance model or subroutines. In this document, this larger code is referred to as the *host code*.

The purpose of FINIX is to provide the host code all the required fuel behavior subroutines via an interface that integrates directly with the host code on the source code level, and only requires a limited number of function calls between FINIX and the host. All the data between the host code and FINIX is passed as arguments of the function calls; no input or output files for the data exchange are needed. This makes execution of the subroutines faster, because disk access is minimized, and also allows the user of the host code to specify which output from FINIX (if any) is saved as a file.

Although the communication between FINIX and the host code is handled without input/output files, since FINIX-0.13.9 it has been possible to initialize FINIX for accumulated burnup using FRAPCON-generated FRAPTRAN restart files, and since version 0.15.6 it has been possible to initialize FINIX data structures by using input files.

FINIX has an error message system, which is designed to provide the host code run-time errors and warnings. For example, convergence failures or invalid correlation parameters would be passed as an error message to the host code. A more detailed description of the error message system is given below.

The setup and usage of the FINIX model is done via built-in functions, which can be used to provide default values for system parameters, give the spatial discretization and, to solve the thermo-mechanical model. A more thorough walkthrough of the procedure is given below, in Sec. 8.6. The source code also includes an example file, *host.c*, which provides FINIX with the necessary run-time data and shows how the model is initialized and run.

A more detailed documentation of the source code, with function descriptions and dependencies, is also given as a separate document automatically generated by Doxygen.

8.2 Units

FINIX functions always use the base SI units in both input arguments and in output. For example, distances are given in meters (m), temperatures are given in Kelvin (K) and power, linear power, and power density are given in W, W·m⁻¹ and W·m⁻³, respectively. The user is responsible for writing any unit conversion functions between the host code and FINIX.

In general, the data in FINIX input files should be given in SI units as well. However, time-related data can be given in seconds, hours or days. If the input will be read from a FRAPTRAN input file, it is possible to choose either British or SI units.

In FINIX, the term "power" refers primarily to thermal power, as opposed to fission power. Currently the code makes no distinction between the two. However, in principle the user should always supply FINIX with the *thermal* power history, including the decay heat of the fission products.

The cold state in FINIX specifies the reference temperature for the fill gas properties and thermal strains. The cold state for thermal strains is defined as 300 K, and the cold state for fill gas properties can be set in the input.
8.3 Data structures

The main purpose of FINIX is to provide the host code the temperature distribution and spatial deformations of the pellet and cladding by using the power history and coolant conditions provided by the host code as input. In addition to these primary data, there are data that are either required by FINIX as parameters, or are generated by solution of the thermo-mechanical model. Although much of this may be irrelevant to the host code, this data is required to continue the FINIX simulation for several consecutive time steps. All the data that FINIX uses or produces is stored in six structures. These structures are described below.

8.3.1 Main structures

The structure called Rod contains the data that describes the physical properties of the fuel rod. These properties include rod dimensions, pellet properties, cladding properties, gas properties and bundle dimensions. This data will not change during simulation. The contents of the Rod structure can be read from the corresponding input file.

The Boundary_conditions structure is used for storing the boundary condition data needed by FINIX. This data includes variables that specify the simulation time, power data, and the data related to cladding and coolant conditions. For each FINIX calculation time step, the Boundary_conditions structure needs to be updated either by the host code, or in the FINIX main program (in host.c).

The Scenario structure contains power profile and irradiation history data that will be read from an input file if needed. Once this data has been read from an input file, it will not change during simulation. The history data from the Scenario structure should be transferred to Boundary_conditions structure at each time step. If the host code provides the boundary condition data, the Scenario structure is not needed. The contents of the Scenario structure can be read from the corresponding input file.

The Results structure contains the simulation results calculated by FINIX that are relevant to the end user.

The Options structure contains the variables that specify the nodalization and the calculation options. This data will not change during simulation. The contents of the Options structure can be read from the corresponding input file.

The Workspace structure contains internal FINIX arrays that FINIX uses for internal calculations and variables that FINIX calculates but are not that relevant for the end user to know. Some of the values are saved between time steps so that time derivatives for various models can be calculated, and some values are cumulative. The structure also allows for efficient memory allocation in FINIX.

8.3.2 Auxiliary structures

Some structures are used to store similar data across FINIX. These are mostly members of the Results structure, but are also found elsewhere.

The Cylindrical structure is used in storing values of results in each component in cylindrical coordinates, that is, values for strains and stresses in the mechanical model. Some members of the Results structure are Cylindrical structures. The Cylindrical structure contains members hoop, axial and radial, and functions for easy manipulation of these structures are implemented. With these functions one can, for example, the copy the values of structures into another or perform simple calculations with them.

Special prefixes: construct_, destruct_, allocate_, append_, create_, free_

The GasComposition structure is used to store values related to fill gas components. Currently, it stores values for the following components: helium, argon, krypton, xenon, hydrogen, nitrogen and water vapor.

The GasConcentration structure is used to store the concentrations of fission gases at different microstructural locations. The stored values are the total produced fission gas, fission gas at the grain boundary, fission gas within the grains and the released fission gas. The local FGR at any node can be calculated as the ratio of the total produced and released fission gases.

The Actinides structure is used to store values related to the following actinide nuclides: $^{235}\text{U}$, $^{238}\text{U}$, $^{239}\text{Pu}$, $^{240}\text{Pu}$, $^{241}\text{Pu}$ and $^{242}\text{Pu}$. The structure is used in members of the Workspace structure and in the radial power distribution model.

8.4 Function naming conventions

As of FINIX-0.17.12, the function naming scheme has been unified across the code. All function names begin with the prefix finix_ to identify them as FINIX functions. Next is the source code file identifier, for example, transient_ for transient.c. Finally, the description of the function is given. In table 7, the adopted prefixes for each source code file are given. From this list, the source code file of each function is easily found.

8.5 Error message system

FINIX uses an error message system to inform the user of issues such as convergence failures, parameters exceeding correlations’ range of validity, etc. The function that encounters the issue returns the pointer to the error message. The message is then passed down, and further error messages are appended to it, until the message reaches the host code. It is then the responsibility of the host code to act on the error message by printing it on screen, writing it on
disc, aborting the program execution, or otherwise. FINIX will not terminate the execution, if an issue is encountered. Only the error message will be returned.

The format of the error message is an array of text strings, formally of type char**. If no errors have occurred, then the top-level pointer will have a value of NULL. This can be used to distinguish between error-free and faulty operation of the FINIX functions. If the value is different from NULL, then the return value contains an error message. The returned array then contains pointers to the error message strings (of type char*). The last message is followed by a NULL pointer, which is used as a marker to terminate the message.

In practice, the user can use built-in functions to deal with FINIX the error messages. One merely needs to declare the pointer in the host code. For example, the following lines will declare the pointer, then call the FINIX transient solver function, catch the error message, print it on screen if it is not empty (i.e., non-NULL), and finally free the memory allocated to the error message.

```c
char **err=NULL;

err=finix_transient_solve(bc->dt, rod, bc, results, options, workspace);
if (err!=NULL) { finix_printf_err(err); }
finix_free_err(&err);
```

### 8.6 System setup and simulation

#### 8.6.1 Initialization

To use the FINIX code in a coupled system, the user must declare the necessary data structures in the host code, initialize the FINIX structures, and calculate the initial state of the simulation by using FINIX functions. After this the model can be run for as many time steps as needed. FINIX comes with an example host code file, `host.c`, which should be replaced in its entirety by the host code. The `host.c` file can be used as an example on how to setup the model. The minimal necessary steps to get FINIX up and running is described in this chapter.

In a coupled system the user is responsible for using an appropriate time step. Although the FINIX algorithms remain stable for very long time steps (longer than several days), discretization error can not be avoided. For relatively slow transients, a time step of the order of 1 millisecond should give very small discretization error during the transient, although for a fast RIA, a considerably smaller time step ($\Delta t \approx 10^{-5}$ s) may be needed.

The declaration and the definition of the variables can be done as follows:

```c
// Declare and construct FINIX data structures
Rod *rod = finix_construct_rod();
Boundary_conditions *bc = finix_construct_bc();
Scenario *scenario = finix_construct_scenario();
Results *results = finix_construct_results();
Options *options = finix_construct_options();
Workspace *workspace = finix_construct_workspace();

// Declare FINIX error message strings
char **finix_err=NULL, **new_err=NULL;
```

The next step is to initialize the system. The FINIX data structures can be initialized by calling the function `finix_init_data_structures()`. The function reads the input files given by the
user, and transfers the data from the input files to the data structures. If no input files are given or some of the input is missing, the above constructor functions initialize the missing data with default values. As default, the data structure initialization function selects the rod, scenario and options to be used based on what identifier is given in the input file. Alternatively, one may select the rod, scenario and options to be used from within the host code with the function `finix_init_choose_input()`. When using this function, the keyword `from_host` must be used in the input files. The choices are given as follows, before the call to function `finix_init_data_structures()`:

// Choose the input file segment to use
finix_err = finix_init_choose_input(rod, "rodID", scenario, "scenID", options, "optionsID");
if (finix_err != NULL) finix_printf_err(finix_err);
finix_free_err(&finix_err);

Before the actual simulation, the steady-state is solved so that FINIX internal structures for many of the parameters are initialized with more realistic values. For this purpose FINIX has the function `finix_steady_state_solve_initial()`, which solves the steady state heat equation and the corresponding mechanical equilibrium for the cladding. This function is a wrapper for the actual steady state solver function, but in which some models are turned off and cumulative values are not updated.

FINIX can be initialized as follows:

// Initialize FINIX data structures
finix_err = finix_init_data_structures(rod, bc, scenario, results, options, workspace);
if (finix_err != NULL) finix_printf_err(finix_err);
finix_free_err(&finix_err);

// Solve initial steady state
finix_err = finix_steady_state_solve_initial(rod, bc, results, options, workspace);
if (finix_err != NULL) finix_printf_err(finix_err);
finix_free_err(&finix_err);

8.6.2 Transient simulation

The transient is solved in distinct time steps defined in the host code, by calling the function `finix_transient_solve()` function. Before each function call, the power density, boundary conditions and other parameters and options can be changed. However, for one time step, i.e., for one function call, they are constant. After each function call, the output of the FINIX model may be saved. For example, one can write FINIX summary files and node-specific files by calling a function `finix_output_print()`.

The transient can be solved for each time step as follows:

// Solve time step with finix_transient_solve()
finix_err = finix_transient_solve(bc->dt, rod, bc, results, options, workspace);
if (finix_err != NULL) finix_printf_err(finix_err);
finix_free_err(&finix_err);

// Update the cumulative simulation time
bc->time += bc->dt;

8.6.3 Steady-state simulation

A steady-state simulation is performed similarly to the transient simulation. The steady-state is solved in distinct time steps defined in the host code, by calling the `finix_steady_state_solve()` function, as follows:

```c
finix_err = finix_steady_state_solve(rod, bc, results, options, workspace);
if (finix_err != NULL) finix_printf_err(finix_err);
finix_free_err(&finix_err);
```

// Update the cumulative simulation time
bc->time += bc->dt;

In contrast with the transient simulation, the densities of fuel and cladding must be updated on each time step. The burnup must also be calculated if it is not provided by the host code. These are performed as follows:

```c
// Calculate density
finix_err = finix_calculate_density(options, rod, results);
if (finix_err != NULL){ finix_printf_err(finix_err); }
finix_free_err(&finix_err);
```

```c
// Calculate burnup
finix_err = finix_steady_state_calculate_burnup(bc->dt, options, rod, results, bc, workspace);
if (finix_err != NULL){ finix_printf_err(finix_err); }
finix_free_err(&finix_err);
```

8.6.4 Updating boundary conditions

As mentioned before, the above lines of code are the minimal setup that is needed to run FINIX in a coupled system. However, if the host code cannot provide all the necessary boundary conditions, the missing boundary conditions must be given in FINIX input file finix_scenario.inp or otherwise. If given through the input file, the boundary conditions must be updated for each time step by calling the function `finix_data_update_bc()` as follows:

```c
// Update boundary conditions before calling finix_transient_solve()
finix_err = finix_data_update_bc(bc, scenario, options, rod, results, workspace);
if (finix_err != NULL) finix_printf_err(finix_err);
finix_free_err(&finix_err);
```

When using the FINIX internal radial power distribution model, a call to the function `finix_steady_state_radial_power_distribution()` is required before a call to the solver functions. The radial power distribution model modifies the boundary conditions for the time step. The call is performed as follows:

```c
finix_err = finix_steady_state_radial_power_distribution(rod, results, bc, options, workspace);
if (finix_err != NULL){ finix_printf_err(finix_err); }
finix_free_err(&finix_err);
```
Note that the calculated actinide concentrations are only summed with the previous timestep values inside the solver functions.

### 8.6.5 Ending the simulation

When the simulation has been completed and FINIX is no longer needed, the memory allocated for FINIX structures must be free’d. This can be done by using the function `finix_destruct_data_structures()`.  

```c
// Free allocated memory
finix_destruct_data_structures(rod, bc, scenario, results, options, workspace);
```

### 8.7 Input instructions

FINIX uses three input files called `finix_options.inp`, `finix_rod.inp`, and `finix_scenario.inp`. These input files can be used to control the simulation. Each input file contains data for several fuel rods. When a new input is created for a new fuel rod, the input should be appended at the end of the files. An alternative way to control the simulation is to use FRAPTRAN input files.

In a coupled system, where all boundary conditions are given by the host code, no input files are required. If no input files are used, default values for simulation options and rod properties will be used. However, it is advisable to specify simulation options and rod properties in files `finix_options.inp` and `finix_rod.inp` (or otherwise in the host code) to get more realistic results. If the host code cannot provide all the necessary boundary conditions, i.e., the contents of the `Boundary_conditions` structure, the `finix_scenario.inp` file must be used to specify the missing boundary conditions.

If a stand-alone version of FINIX is used, the scenario boundary conditions must be given in file `finix_scenario.inp`. Again, it is advisable but not mandatory to give the simulation options and rod properties in files `finix_options.inp` and `finix_rod.inp`. Alternatively, input can be given in a FRAPTRAN input file. However, even though the rod and scenario parameters are given in a FRAPTRAN input file, it is advisable to specify FINIX simulation options in `finix_options.inp` because FINIX simulation options cannot be set in a FRAPTRAN input file. All the data given in FRAPTRAN input file overwrites the default data and the data read from FINIX input files.

The contents of FINIX input files is organized in data blocks. Each block of data describes one fuel rod. Therefore FINIX needs to know which block of data to read from a file. The data blocks are of the following form:

```plaintext
begin rod_name1
data_1 = x
data_2 = y
data_n = z
end rod_name1
```

As can be seen above, every data block begins with "begin" statement and ends with "end" statement. These statements are followed by the name of the rod. Note that the rod name must not include white spaces. As the data in input files has been grouped into blocks that describe each fuel rod, one should tell FINIX from which data block to read the data. This can be done with the "USE" statement as follows:

```plaintext
USE rod_name1
```
begin rod_name1
data_1 = x
data_2 = y
data_n = z
end rod_name1

begin rod_name2
data_1 = x
data_2 = y
end rod_name2

The "USE" statement tells FINIX that it should read the data from a data block that begins with "begin rod_name1" and ends with "end rod_name1". Every FINIX input file should begin with the "USE" statement.

If the data block is to be selected by the host code, the statement "USE from_host" must be used. When this statement is used, one may give the data block identifiers from within the host code with the function finix_init_choose_input().

The data in input files can be arranged in any order. After a keyword, there should be an "=" sign followed by the data that corresponds to the keyword. If the data consists of several values, they should be separated with commas. The lines in input files that begin with "!", "*", or "/" are commented lines, and FINIX will ignore them. The contents of the three input files is described in the following chapters.

8.7.1 Input file finix_options.inp

Input file finix_options.inp can be used to set FINIX nodalization and to select the models FINIX uses during simulation. Table 8 shows the data that can be given in finix_options.inp. If default value will be used, it is not necessary to add that data in the input file. The contents of a file could look like this:

USE rod_123

begin rod_123
axial_nodes = 10
pellet_radial_nodes = 15
boundary_option = 0
end rod_123

Now the rod will be divided to 10 axial nodes and the fuel pellet will be divided to 15 radial nodes. The rod outer surface temperature will be given by the user. For the rest of the keywords default values shown in Table 8 will be used.

Input file finix_options.inp has also a special purpose. It can be used to tell FINIX that the input will be read from a FRAPTRAN input file. In this case the the first line of the file should read "USE FRAPTRAN". When FINIX simulation begins, it asks the user the name of the FRAPTRAN input file and the name of the FRAPCON generated restart file. If FRAPTRAN input file will be read, the contents of the finix_options.inp could look like this:

USE FRAPTRAN

or like this:
USE FRAPTRAN

begin FRAPTRAN
axial_nodes = 10
pellet_radial_nodes = 15
boundary_option = 0;
end FRAPTRAN

In the first case all the data will be read from a FRAPTRAN input file. In the second case nodalization and boundary option will be given in finix_options.inp. If nodalization is also given in FRAPTRAN input file, the data given in FRAPTRAN input file overwrites the data given in finix_options.inp. Note that the variables that specify FINIX model selections should always be given in finix_options.inp. If the input will be read from the FRAPTRAN input file, input files finix_rod.inp and finix_scenario.inp will be ignored.

</tr>
</tbody>
</table>
8.7.2 Input file finix_rod.inp

Input file finix_rod.inp can be used to determine the fuel rod properties. Table 9 shows the data that can be given in finix_rod.inp. The contents of a file could look like this:

```
USE rod_123

begin rod_123
fuel_length = 4.0
clad_length = 4.0
plenum_length = 0.4
end rod_123
```

In this case default values will be used for all the parameters except for fuel, clad, and plenum length.

8.7.3 Input file finix_scenario.inp

Input file finix_scenario.inp can be used to determine the rod conditions during an irradiation or experiment period. As mentioned before, this data must be given if FINIX is used as a stand-alone version, or the host code cannot provide all the necessary boundary conditions. Table 10 shows the data that can be given in finix_scenario.inp. Note that it is not necessary to give all the data presented in Table 10 to fully determine the boundary conditions. For example, if the user has chosen to use coolant bulk temperature as boundary condition (boundary_option = 3), it is not necessary to determine the clad temperature history in finix_scenario.inp. The contents of the file finix_scenario.inp could look like this:

```
USE rod_xyz

begin rod_xyz
restartfile = imprestart.rod_xyz
end_time = 1.0

time_step_history =
0.0001, 0.0,
0.00001, 0.0702,
0.0001, 0.0815,
0.001, 0.210

power_history =
0.0, 0.0,
524934.384, 0.066,
23622047.28, 0.079,
5511811.032, 0.079,
262467.192, 0.095,
0.0, 0.1

axial_power_profile =
0.728, 0.0,
0.975, 0.099,
1.156, 0.259,
1.053, 0.420,
0.668, 0.569
```
coolant_temperature_history_zones = 0.373, 0.569
coolant_temperature_history(1) =
553.15, 0.0,
1023.15, 0.2,
1048.15, 0.4,
753.15, 1.0
coolant_temperature_history(2) =
553.15, 0.0,
878.15, 0.2,
923.15, 0.4,
948.15, 1.0

heat_transfer_coefficient_history_zones = 0.569
heat_transfer_coefficient_history(1) = 2000000.0, 0.0

coolant_pressure_history = 0.5e6, 0.0
end rod_xyz

As can be seen in the example above, the history data is always given in data pairs. For example, the time step history is given so that the first value of the data pair is the length of the time step, and the second value is the time at which this time step length takes effect. This time step length is used until a new data pair is given. Similar logic applies to other history data as well.

All time-related FINIX input can be given in seconds, hours or days. The units of the time can be selected by modifying the value of time_unit in finix_scenario.inp. Note that all the time-related data in Table 10 is expressed in seconds (default) only for clarity. The time units of the data shown in Table 10 depends on the value of time_unit. The value of time_unit also determines the units of the time in output files finix.z* and finix.sum.

In the example above one can also see that some of the history data, such as the coolant temperature history, can be given separately for different axial zones. In this case the coolant temperature history has been given for axial zones 1 and 2. The number of zones does not have to match the number of axial nodes given in finix_options.inp. FINIX will automatically calculate history data for each axial node based on the data given for each zone. Note that one should also determine the top elevations of each zone from the rod bottom. In the example above, the top of the first coolant temperature history zone is 0.373 m above the rod bottom, while the top of the second zone is 0.569 m above the rod bottom.

8.8 Output files

FINIX includes functions that can be used to print output files for many purposes. One aim of this chapter is to describe the contents of these output files. In addition, this chapter shows how to call the output writing functions from the host code.

8.8.1 finix.sum and finix.z*

The data describing the behaviour of a fuel rod as a function of time is presented in output files finix.sum and finix.z*. The contents of these files is presented in Tables 11 and 12. Output file finix.sum contains rod summary data, while output files finix.z* contain node-specific data. Node-specific output files are written for each axial node. Asterisk (*) in the aforementioned file names represents the node number.

By default, the cumulative simulation time in files finix.sum and finix.z* is given in seconds. However, the simulation time in the aforementioned files will be given in hours or days if a non-default value is given for keyword "time_unit" in finix_scenario.inp. In other words, the same units of time are used in files finix_scenario.inp, finix.sum and finix.z*.

To print these output files, the following additional lines of code must be included in the host code:

```c
// Declare a structure containing file pointers to output files
Output *files;

// Initialize output writing to finix.sum and finix.z files
files = finix_outputInitialize(options);
```

In the initialization call above the type of the function parameter is Options*. After declarations and initializations the output writing function can be called for each time step as follows:

```c
finix_outputPrint(files, rod, bc, options, results);
```

Here the types of the function parameters are Output*, Rod*, Boundary_conditions*, Options*, and Results*. After the output files have been printed, they must be closed and the memory must be free’d. This can be done as follows:

```c
// Close files and free allocated memory
finix_outputClose(files, options);
```

8.8.2 finix_data_structures.dbg

Output file finix_data_structures.dbg shows all the data stored in FINIX data structures at the time of the output writing call. The function is called during FINIX initialization by default, but it can be called later again if needed. The output file is especially useful for checking that the input files have been read corectly. The output file finix_data_structures.dbg can be printed by calling a function

```c
finix_outputPrintDataStructures(rod, bc, scenario, results, options);
```

where the function parameter types are Rod*, Boundary_conditions*, Scenario*, Results*, and Options*.

8.8.3 finix_stripfile.txt

Output file finix_stripfile.txt contains data in FRAPTRAN stripfile format. The file describes the state of the fuel rod at various time steps.

To print this output file, the following additional lines of code must be included in the host code:

```c
// Declare a variable for printing the results
FILE *writefile;

// Open the file
writefile = fopen("finix_stripfile.txt","w");

// Print the header lines
finix_output_fprintf_stripfile(0, writefile, bc->time, results, rod, options, bc);
```

After these steps the output writing function can be called for each time step as follows:

```c
finix_output_fprintf_stripfile(1, writefile, bc->time, results, rod, options, bc);
```

After the file has been printed, it must be closed:

```c
fclose(writefile);
```

9. Code assessment

9.1 General performance

The validation of FINIX-0.13.9 is presented in a separate validation report [1], where the detailed results can be found. Version 0.17.12 will be validated in the future. Some remarks on the effects of the new models in version 0.17.12 and a brief summary of FINIX-0.13.9 validation are given below.

FINIX-0.17.12 includes several models important for the accurate description of long irradiations. Some limitations are still present: for example, cladding oxidation or high-temperature creep are not modeled.

FINIX-0.13.9 has been compared against experimental centerline temperature data from Halden steady state irradiation experiments IFA-429 and IFA-432. The agreement between simulated and experimental results is good. For low burnup, the results match very well. With increasing burnup, the match becomes worse, although FINIX and the experimental value typically agree within roughly 100 K, with FINIX having a slight tendency to underestimate the centerline temperature. The poorer performance at higher burnups is expected, as FINIX does not have models to describe many of the burnup-dependent phenomena, such as fuel densification and swelling, cladding creep and fission gas release. Although these can be taken into account when initializing FINIX for transient calculations, simulating their behavior during long-term irradiation is not possible in the present version.
FINIX-0.13.9 was also validated against FRAPTRAN simulations of selected reactivity initiated accidents. The results for FRAPTRAN are described in the FRAPTRAN code assessment document [43], while the FINIX results and the comparison are discussed in the FINIX-0.13.9 validation report [1]. The cases consisted of RIA’s with western and VVER type fuel rods, some of which had failed during the experiment, and some had not. In some of scenarios significant plastic deformation of the cladding was indicated by FRAPTRAN, while in some very little permanent deformation occurred. All the cases were initialized for non-fresh fuel using FRAPCON for steady state irradiation.

The comparison between FINIX and FRAPTRAN shows very good agreement between the codes. In almost all the cases, the fuel and cladding temperatures are very closely reproduced. Even in the cases where the cladding deforms plastically, FINIX succeeds in calculating the temperatures with good accuracy, although the differences in the gap dimensions and conductance are clearly seen. In addition, the cases where the rod fails are calculated very similarly up to the point of failure, after which FRAPTRAN switches to a different model. FINIX-0.13.9 had no criteria to determine rod failure, and therefore the calculation proceeds somewhat differently from the FRAPTRAN solution. FINIX-0.17.12 is expected to proceed more similarly to FRAPTRAN.

9.2 Preliminary validation of new steady-state models

9.2.1 Steady-state heat equation solver

The new steady-state heat equation solver was thoroughly tested by Valtavirta [6]. The temperature distribution in steady-state calculations is affected greatly by the new burnup-dependent models implemented in FINIX-0.17.12. In figure 2 the results calculated with FINIX-0.17.12 are compared with the previous version and experimental data. The new temperature predictions are much closer to experimentally determined temperatures.

9.2.2 Cladding creep model

The creep models were validated against the IFA-585 [44] and IFA-699 [45] creep tests performed at the Halden reactor. A host code for only the creep model was written to estimate the performance of only this model. The BWR rod from the IFA-585 test and the Zircaloy-4 segment from the IFA-699 test were used as test cases. The calculated creep strain values are compared to the experimental values in figure 3. The Geelhood model implemented in the code is otherwise similar to the Limbäck-Andersson model, but the driving force of primary creep is set to be effective stress change, not effective stress, and its sign is the sign of the effective stress change. Also, the Geelhood model initializes the time of the creep correlation on each time step, so it has no memory of previous deformations and therefore no strain hardening between stress steps.

9.2.3 Fission gas release model

The fission gas release model was verified against VTT-modified FRAPCON-4.0, in which the Pastore et al. fission gas release model was implemented. The modified FRAPCON-4.0 version has been initially verified against the BISON implementation of the Pastore et al. model [46]. It was found that most differences can be ascribed to difference in temperature. A verification case where a fuel rod is irradiated at 25 kW-m\(^{-1}\) was used to verify the FINIX implementation against the VTT-FRAPCON-4.0 implementation. The temperature in FINIX tended to be higher
than in FRAPCON at higher burnup, which affected the results. Similar behavior was seen with a comparison of FRAPCON and BISON, but in BISON the temperature diverged from FRAPCON at a higher burnup [46]. The FRAPCON-4.0 gap conductance correlation was used in both codes. The use of the FRAPCON-3.4 correlation would yield higher temperatures.

For the verification, some parameters in FINIX were set to have the values used in the VTT-modified FRAPCON, and vice versa. These are:

- the most recent three-term Turnbull fission gas atom diffusion coefficient [38] in FINIX was changed to an older one with two terms [37],
- the intergranular bubble number density evolution equation in VTT-FRAPCON-4.0 was changed to that derived by Pastore et al. [29], instead of that reported by White [47],
- The vacancy diffusion coefficient from [29] in FINIX was changed to a value used in VTT-FRAPCON-4.0,
- The coefficients $A_n$ of the integration kernel in the Forsberg-Massih model in FINIX were set to the values in FRAPCON-4.0, instead of the values reported by Hermansson and Massih [26], and
- the grain growth model was turned off in both codes.

In figures 4, 5 and 6 the temperatures, fission gas distribution and fractional coverage from FINIX and VTT-FRAPCON-4.0 are compared. The differences in the distribution of fission gases between grains, grain boundaries and free volume can be explained by the higher temperatures calculated by FINIX at higher burnups.

A limited validation was also performed with the FINIX models modified in the verification returned to their default values. The results are shown in table 13.

9.2.4 Radial power distribution model

The radial power distribution calculated by the FINIX TUBRNP implementation was validated with the results from the paper by Lassmann [32]. Experimental results for fuels with burnups between 27.6 and 31.65 MWd·kg⁻¹ from figure 1(b) of the paper were graphically extracted and compared with results calculated with FINIX at 30 MWd·kg⁻¹. The agreement is similar to that reported in the paper.
Figure 7. Total plutonium concentrations calculated with the FINIX TUBRNP implementation at 30 MWd-kg\(_U\)\(^1\) compared to experimentally measured data for fuels with burnups between 27.6 and 31.65 MWd-kg\(_U\)\(^1\). Data from figure 1(b) in [32].
9.3 Solved issues from previous versions

A steady-state heat equation solver was implemented, which decreases computation time in steady-state calculations. Multiple models required for long irradiation periods have been implemented in the new version, so long irradiations can be modeled with FINIX with better accuracy.

In the version FINIX-0.15.12 only outwards plastic deformation could occur due to a bug. The bug was removed and plastic deformation can now occur inwards or outwards.

A bug in the radial return algorithm, where the calculated effective plastic strain increment was subtracted twice from the trial stress, was corrected. The radial return algorithm is now more stable.

The rod internal pressure calculated by the secant method in FINIX-0.15.12 was not actually used in the cladding mechanical model, and instead the internal pressure calculation was only a fixed-point iteration scheme. Now this is corrected, and one may select within the source code between the bisection, secant and false position methods. The secant method is selected as default.

9.4 Known issues and possible caveats

As shown in [1], the performance is very good for temperature calculations. However, a number of issues remain to solved. These are:

- The pressure calculated by FINIX typically differs somewhat from that calculated by FRAPTRAN. The most probable cause for this is a difference in the rod free volume, possibly in the volume of the plenum. The plenum temperature is also calculated in a different way, but the difference exists already for zero power.

- The plastic strains read from a FRAPCON restart file are treated differently by FINIX and FRAPTRAN. It is not exactly clear how FRAPTRAN treats the plastic deformations, but it seems that this is a source of some of the discrepancies between FINIX and FRAPTRAN.

- With a large amount of radial nodes (> 100), the steady-state heat equation solver calculates slightly different temperatures compared to the transient solver. The cause of this discrepancy is not known at this time. Numerical instability may also result from using a too large amount of radial nodes.

In addition to the technical issues, one should keep in mind the limitations of the FINIX models:

- In many cases, when the range of validity of a model is exceeded, FINIX will not crash or abort execution. Instead, the solver will do its task and pass an error message. It is the responsibility of the user to catch the message and act accordingly. Calls to FINIX functions should always be accompanied by error message checking.

- The coolant model of FINIX is very limited. The model is not reliable beyond nucleate boiling. A warning message is issued if the critical heat flux is exceeded. Also, in FINIX-0.15.12 the temperature of the coolant is not affected by the outward heat flux from the rod. This will affect temperatures at the upper part of the rod, if no external model for the coolant temperature is used.

- The FINIX-0.17.12 creep model is the same model that is used in traditional fuel performance codes, but such models have been shown to be valid only with increasing stress on the cladding. Therefore the creep strains calculated by FINIX-0.17.12 may be erro-
neous when modeling fuel rods where stress reversal on the cladding occurs (compressive stress turns into tensile or vice versa).

- The fission gas release model in FINIX-0.17.12 underestimates the fission gas release, and additional models should be implemented.

- FINIX-0.17.12 rod failure criterion is conservative.

- FINIX-0.17.12 plastic deformation model is limited to infinitesimal deformations. Scenarios such as cladding ballooning where finite deformation takes place are therefore not realistically modeled.

- FINIX-0.17.12 contains only a low-temperature creep model, and high-temperature creep such as that in a LOCA scenario is not yet modeled.

- The burnup calculation of FINIX does not differentiate between the thermal and fission power. The results are indicative, and generally accurate within roughly 5–10% of the experimentally determined values. When using FINIX with a host code which calculates a more accurate burnup, it is advised to input this burnup into FINIX.

- The FINIX radial power distribution model does not take into account the effect of burnable poisons.

- The cladding plasticity calculation requires a sufficiently small time step so that the calculation converges. Currently there is no automatic substepping algorithm in FINIX, so a sufficiently small time step must be used if gap conductance does not converge.

## 10. Summary

The FINIX fuel behavior code has been updated to version 0.17.12. In this version a new solver of the steady-state heat equation is implemented along with several models important in modeling long irradiations: fission gas release, pellet swelling and densification and cladding creep.

Validation of the stand-alone FINIX-0.13.9 has been done in a separate report [1]. Results show good performance in RIA and steady state scenarios. Especially the temperature distributions are reliably calculated. Limitations have been discussed in Section 9. The validation of version 0.17.12 is to be done in the future.

The primary purpose of the FINIX code is to provide a fuel behavior module for other simulation codes in multiphysics simulations. The intended use is the improvement of fuel behavior description in neutronics, thermal hydraulics and reactor dynamics codes, without having to employ the available full-scale fuel performance codes. FINIX couples with the host code on a source code level, and provides an interface of functions that can be used to access the fuel behavior model from the host code. The required knowledge on the correlation-level details and rod parameters has been minimized by defining default templates that can be used without having information on all model-specific details.

Currently FINIX has been integrated into the Monte Carlo reactor physics code Serpent 2, where FINIX serves as the default fuel behavior module. In addition to Serpent, FINIX has been integrated into VTT’s reactor dynamics codes TRAB-1D, TRAB3D and HEXTRAN. Results have been reported, for example, in Refs. [14, 12, 13, 8].
